In order rightly to appreciate the value of his work, it is necessary to understand what were the conditions which obtained when he became Superintendent of the Royal Albert Asylum. At that time, although there were in the country a few excellent institutions for defectives, the methods for training such persons were empirical, and for the most part haphazard, rather than based upon any scientific principles. Shuttleworth's keen interest in physiology (he had taken his degree at London University with honours in this subject) enabled him to appreciate to the full the physiological principles of training which had been described in 1864 by Dr. E. Seguin of America, and he became an enthusiastic user and teacher of these methods. Under his guidance and zeal the Royal Albert soon acquired a world-wide reputation, and visitors from all parts came there to gain instruction in the scientific training of defectives. When Shuttleworth left Lancaster in 1893 and came to London, one of his chief concerns was to organise classes of instruction for teachers and nurses who were going to take up the care of defectives, and the majority of those who are now prominent in this work owe their training to him. Beyond the handful of training institutions in existence at that time there was no provision whatever for the education of the mass of defectives throughout the country; indeed, officials and the general public were blind to the fact that any considerable number of defectives existed. There is not the slightest doubt that the propaganda undertaken by Shuttleworth and his little band of disciples had a very important influence in educating official and public opinion as to the claims of the mentally defective, and in the provision of those educational facilities which we have to-day. Shuttleworth was the leading expert member of the Board of Education Departmental Committee which was set up to inquire into this matter. The report of this committee led to the passing of the Defective and Epileptic Children Act of 1899, and this Act was the foundation of the whole system of special education for children of the public elementary school class which now exists in this country.

Shuttleworth made many important literary contributions to the subject. His first publication was an account of "Two Cases of Microcephalic Idiocy," in 1875. He also wrote valuable articles in the Encyclopædia Medica, Allbutt's System of Medicine, Hack Tuke's Dictionary of Psychological Medicine, and numerous journals. The writing by which he is chiefly known, however, is his very valuable and practical little book on "Mentally Deficient Children, their Treatment and Training." This was first published in 1895. It was at once recognised as a standard book, and was largely used by medical men and teachers. A fifth edition, in which Dr. W. A. Potts collaborated, was published in 1922.

Dr. A. F. Tredgold writes: "At the present time this country, in regard to its laws, its training establishments, its methods and availability of education, its courses of instruction for students and teachers, its clinical research and literature, and its general care and treatment of the mentally deficient, occupies a leading place. This position is due in no small measure to the writings and teaching, the propaganda and pioneer work, and the life devotion of Shuttleworth. His personality was such as to endear him to all who were brought into contact with him. Although in talking to him one was at once conscious of his wide knowledge and ability, the outstanding impressions which he produced were those of an absolutely sincere, sympathetic, kind-hearted, and unassuming man. There must be many to-day who will remember and be grateful for his shrewd advice and kindly sympathy. The writer had the privilege of knowing him for close on 30 years, and mourns the loss of one who was always a true friend and wise counsellor."

JOSEPH THOMPSON CARSON, M.B., F.R.C.S.EDIN.

AT the early age of 43 Dr. J. T. Carson died at Dover on May 30th. An Ulsterman by birth, he graduated in medicine at Edinburgh in 1908, afterwards gaining general experience as house surgeon at infirmaries at South Shields, and at Bolton, at Birkenhead Borough Hospital, and elsewhere. During the late war he held a captain's commission in the Royal Army Medical Corps, and served as radiologist to the 28th General Hospital at Salonika from 1915 to 1918. Afterwards he settled in practice at Oldham, and finally at Dover, where he was honorary surgeon to the hospital, having taken the Fellowship of the Royal College of Surgeons of Edinburgh in 1922. Two years ago he developed signs of splenomedullary leukæmia, but though aware of his condition, he continued his work to the last.

THE LATE SIR JAMES HODSDON.

Dr. James Burnett sends the following words of tribute to the memory of the late Sir James Hodsdon, whose obituary notice appeared in THE LANCET last week. "As a physician," he writes, "I feel it my duty to pay a tribute to the memory of my old teacher, Sir James Hodsdon. I was a member of his class at Surgeon's Hall in 1896. At that time he had the largest following of all the extramural lecturers on surgery. To the outward observer he appeared brusque, almost unkindly, in his manner, but that was on the surface; beneath a somewhat stand-off exterior there beat a most kindly and sympathetic heart. To know the man was to admire him, to respect him, to love him; for he was a man of very deep feeling, and his first thought and care were always for others. Hodsdon was not what is commonly known as a "brilliant" surgeon, but his results were beyond criticism. Quiet, and somewhat dogmatic in manner, as has been implied, he could be trusted to carry out any surgical operation with skill, care, and precision. Every seemingly trivial procedure was accomplished with the same attention to minute details and the well-being of the

patient as would be given in a major operation. He always put the patient first. As a lecturer he was at his best. His course on surgery was for many years recognised by students as the most complete and the most instructive that could be obtained in the Edinburgh School, and it is probably as a lecturer that Hodsdon will be remembered best, for so many graduates to-day owe to him their early knowledge of the art and science of surgery. In Edinburgh his name will be revered with those of Armandale and Alexis Thomson; these three, in fact, probably forming the most outstanding trio of surgeons Edinburgh has produced in recent times."

A further tribute from a younger pupil shows how long and how deep the influence was of Hodsdon's teachings: "When Hodsdon commenced systematic teaching in Minto House, many lectures were being delivered by more eminent men, but it was soon seen that Hodsdon's were the finest; his course was more of an advanced type and attracted the senior students, while he was intensely interested in the work and took infinite trouble in the preparation of his deliveries, bringing them to such a state of excellence that, later, when he continued at the Surgeon's Hall, he attracted a large class, all of whom will remember the lessons learnt from him with vividness. In the wards of the Royal Infirmary he ever displayed his special interest in his patients; his operative ability, sound technique, and painstaking after-care quickly endeared him to them and gave them an unusual confidence. His clinique followed his work with the greatest interest, and learned under him a practice of surgery never to be forgotten."

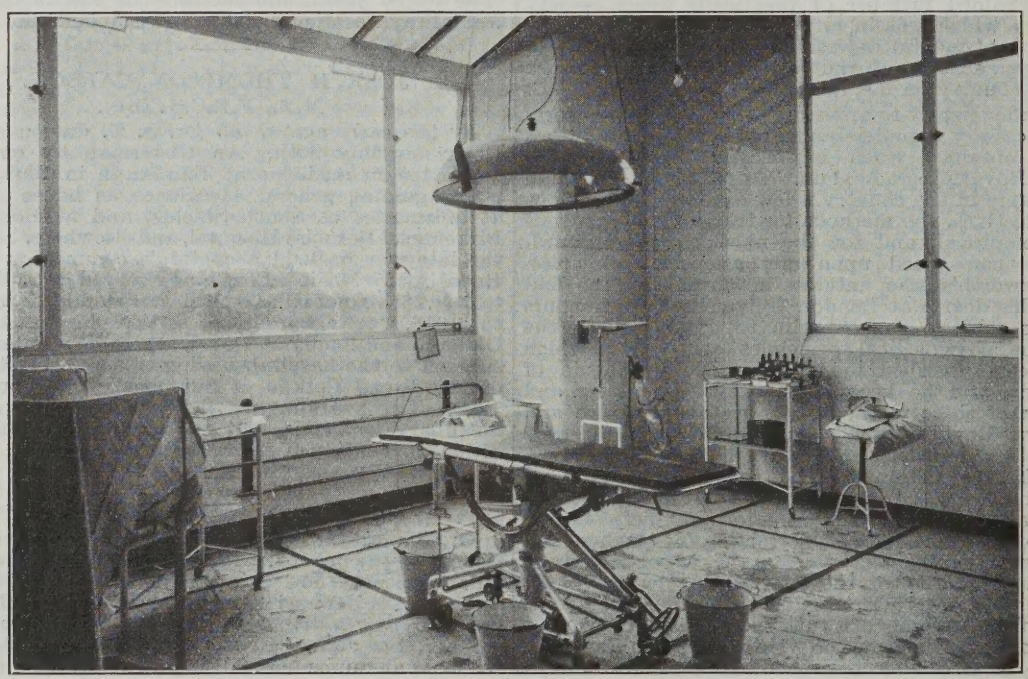
NEW OPERATING THEATRES AT CAMBRIDGE.

EXTENSION OF ADDENBROOKE'S HOSPITAL.

ON Friday, June 1st, Sir Berkeley Moynihan, President of the Royal College of Surgeons, opened two new operating theatres and a maternity ward which have been added to Addenbrooke's Hospital, Cambridge.

Before the ceremony a luncheon was given by the staff of the hospital at Downing College, by permission of the Master and Fellows. Sir Hugh Anderson, Master of Caius College, presided, and many members of the University and representatives of the medical profession in Cambridge and the surrounding counties were present.

After the luncheon Sir Berkeley Moynihan inspected the new operating theatres and maternity ward, and at 3 o'clock the opening ceremony was held in the casualty department of the hospital, in the presence of a large gathering. Mr. T. Musgrave Francis (chairman of the general committee) took the chair. He was supported by Mr. C. R. W. Adeane (president of the hospital), the Rev. G. A. Weekes (Vice-chancellor of the University), Councillor E. W. Amies (Mayor of Cambridge), and Dr. E. H. Parker. The Chairman, introducing Sir Berkeley Moynihan, spoke of the gratification felt at his presence, and hoped that he might look with favour upon the new theatres and the further schemes for enlargement and improvement of the hospital. He also extended a welcome to Lord Knutsford (chairman of the London Hospital), who was among the guests, and with a reference to the venerated memory of the late Regius Professor, Sir Clifford Allbutt, who, like Sir Berkeley, came from Leeds, expressed regret that Sir Humphry Rolleston, Sir Clifford's successor, was unable to be present that afternoon.



One of the new operating theatres at Addenbrooke's Hospital.

[*Photograph by the "Cambridge Chronicle."*]

Sir Berkeley Moynihan then delivered the address which we publish on page 1207. The proceedings ended with a vote of thanks by Mr. Adeane, seconded by the Vice-chancellor, who expressed a hope that when the University's new school of physiology was open there would be greater coördination between surgery and physiological science in Cambridge.

The new theatres, of which we publish an illustration, are on the third floor, and were designed by Mr. Kay, of Leicester, the work being carried out by Messrs. Martin and Co., of Northampton. The theatres and adjoining rooms cost £10,000 to build.

nd another £1500 to equip. They are thoroughly p-to-date in design and equipment. The space ormerly occupied by the old operating theatre nd two other old wards was used for the new aternity ward. This consists of a labour room, hich can be used as an operating theatre, two nall wards, each with four beds, and several smaller ooms. The cost of the whole was £3500.

Medical News.

UNIVERSITY OF CAMBRIDGE.—Dr. Alfred Ernest arclay has been appointed University Lecturer in Medical adiology and Electrology. Dr. Barclay is at present cturer in radiology in the University of Manchester and on. medical officer of the X ray and electrical departments the Manchester Royal Infirmary.

At a recent congregation the following degrees were nferred :—

M.D.—E. P. Hicks.
M.B., B.Chir.—W. J. Moody and H. A. Clegg.

SOCIETY OF APOTHECARIES OF LONDON.—At recent aminations the following candidates satisfied the examiners the undermentioned subjects :—

Surgery.—M. K. Bryce, London Hosp.; H. M. Feldman, Leeds; H. A. Hennessy, Adelaide and London Hosp.; N. C. R. Keukenschrijver, Amsterdam; C. P. Madden, St. Bart.'s Hosp.; and H. D. K. Wright, St. Bart.'s Hosp.

Medicine.—K. D. C. Beckitt, Manchester and Charing Cross Hosp.; L. J. Corbett, St. Mary's Hosp.; N. C. R. Keukenschrijver, Amsterdam; A. A. Leibovitch, Kharkoff and London Hosp.; and L. W. Sanders, Manchester and Charing Cross Hosp.

Forensic Medicine.—A. C. Banerji, Charing Cross Hosp.; H. I. Jones, St. Mary's Hosp.; and N. C. R. Keukenschrijver, Amsterdam.

Midwifery.—M. K. Bryce, London Hosp.; N. C. R. Keukenschrijver, Amsterdam; and A. E. Vawser, London Hosp.

The Diploma of the Society was granted to the following ndidates, entitling them to practice medicine, surgery, and idwifery: K. D. C. Beckitt, L. J. Corbett, H. I. Jones, . C. R. Keukenschrijver, and L. W. Sanders.

THE MEDICAL INSURANCE AGENCY.—A dinner celebration of the twenty-first anniversary of the Medical nsurance Agency was held at the Hotel Victoria on the vening of May 30th, when the Chairman of the Committee Management, Sir Humphry Rolleston, presided. Among ne guests of the Committee of the Agency were Sir Percy hompson, Deputy Chairman of the Board of Inland evenue; Dr. J. Smith Whitaker, of the Ministry of Health; r. Digby Besant, General Manager and Mr. H. D. O'Neill, ecretary of the Clerical and General Life Assurance ociety; Hon. Evelyn Hubbard, Chairman of the Guardian ssurance Company; Mr. Henry J. Tapscott, General anager, and Mr. A. Moorhouse, actuary of the Century Life ffice; Sir Charters Symonds, Treasurer of the Royal Medical enevolent Fund; Dr. Vincent Dickinson, Deputy Master the Society of Apothecaries of London; Mr. H. W. arson, President of the Medical Society of London; Dr. J. Allan, Chairman of the Medical Sickness Annuity and fe Assurance Society; Mr. Greville Topin, Scottish Widows' und Life Assurance Society; Dr. N. G. Horner, Editor the British Medical Journal; Dr. James Neal, General ecretary of the Medical Defence Union; Mr. Bertram utton, Secretary of the Medical Sickness Annuity and Life ssurance Society; Mr. Pitt Albert, Sun Life Assurance ociety; Mr. R. H. Burr, Employers' Liability Assurance orporation; Mr. Alex Gibb, Equity and Law Life Assurance ociety; and Mr. E. V. Davidson, Scottish Equitable Life ssurance Society.

After the loyal toasts, given from the chair, Mr. Besant, in roposing "The Medical Insurance Agency," referred to the ccess which under good management had attended the gency from its inception in 1907. At that time the motor- r had hardly begun, while the Workmen's Compensation ct had only just come into being. The new insurance oblems coincided with the genesis of the M.I.A. Noting at the late Mr. Guy Elliston was a tower of strength in e early days of the movement, he said something like ,500,000 of policies had been issued to doctors and their pendents through the Agency, while an enormous sum of oney had been given to medical charities through its edium. Sir Robert Bolam, in reply, said that the M.I.A. alued highly the cordial coöperation of the various insurance odies, while the outstanding features of the Agency were at, while it was able to give the best insurance advice to e medical profession, every penny of surplus went to arities associated with the medical profession. Mr. Ferris-Scott, who also replied, said that competition for the insurance business of medical men was now extraordinarily keen, while among the advantages of insuring with the M.I.A. were the rebates to doctors, which already showed a total saving to the medical profession of over £28,000, nearly £1800 being in respect of 1927; the total distribution to medical charities, by the end of the past year, amounted to £18,091. Referring to the valuable interest which the medical journals took in the Agency, he said that the Editors of *The Lancet* and the *British Medical Journal* were among the founders of the movement, and he mentioned that the M.I.A. had offered Epsom College £500 to establish the first Presentation Scholarship in memory of Sir Dawson Williams. Dr. Langdon-Down, who proposed "The Guests," with which he coupled the names of the Hon. Evelyn Hubbard and Sir Charters Symonds, Royal Medical Benevolent Fund, spoke of the assistance received from the master mariners of insurance by the M.I.A., which in its early days was sailing on unknown seas. Mr. Hubbard, in reply, referred to the voluntary nature of the work done by the M.I.A., saying that, as in his opinion the voluntary system was essential to the general hospitals, so such voluntary help as was given by the M.I.A. was worth ten times as much as official service. Sir Charters Symonds said that he hoped the efforts which the Agency were making to support medical charities would become a universal habit among medical men; it would then be possible to give larger pensions, and more substantial assistance in many worthy directions. Sir Squire Sprigge proposed the health of the chairman.

HARVEIAN SOCIETY OF LONDON.—The annual dinner will be held at the Connaught Rooms, London, on Thursday, June 14th, at 8 P.M.

INDIAN MEDICAL SERVICE DINNER.—The annual dinner will be held at the Trocadero Restaurant, London, on Wednesday, June 20th, at 7.15 P.M., under the chairmanship of Major-General Sir R. Havelock Charles. Particulars may be had from the joint hon. secretary, Major Sir Thomas Carey Evans, 31, Wimpole-street.

LONDON HOSPITAL MEDICAL COLLEGE.—Prizes and certificates will be distributed by Sir Samuel Hoare, Secretary of State and President of the Air Council, in the Library of the College at 3 P.M. on Friday, June 29th, and the distribution will be followed by tea and music in the hospital gardens.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS.—The programme of the summer meetings of the Institution, which will be held this year at Blackpool, from June 18th to 20th, has now been issued. Particulars may be had from the secretary, Mr. H. B. Watt, 12, Russell-square, London, W.C. 1.

BIOCHEMICAL SOCIETY.—A meeting of this Society will be held at Rothamstead Experimental Station, Harpenden, to-day, Saturday, June 9th. The experimental fields and laboratories will be inspected during the forenoon, from 11.15 onwards, and the meeting for business and communications will be held at 2.15 P.M. Further details may be had from the hon. secretary, Mr. R. Robinson, D.Sc., Lister Institute, Chelsea Bridge-road, London, S.W. 1.

FEDERATION OF HEALTH RESORTS OF FRANCE.—The twenty-first Voyage d'Etudes Médicales (V.E.M.) will take place between the dates of Sept. 1st and 12th inclusive. The tour will be under the direction of Dr. Maurice Villaret and Dr. Paul Harvier, respectively Professor and Professor Agrégé of the Faculty of Medicine at Paris, and the trip will be organised by Dr. Janot, secretary of the Thermal Federation of Auvergne. L'Auvergne and Le Bourbonnais will be visited, and the more important health resorts will be arrived at in the following order. Starting at 2 P.M. on Sept. 1st from Pougues, St. Honoré-les-Bains, Bourbon-Lancy, Bourbon-l'Archambault, and Néris-les-Bains will be visited, arrival at La Bourboule being timed for Sept. 4th. On the following day after visiting La Bourboule, the party will be conducted to Mont-Dore through Puy de Sancy and the Plateau des Capucins, dining and sleeping on the evening of Sept. 7th at Vic-sur-Cère. Then, passing through St. Nectaire, the party will visit Royat on Sept. 9th and sleep there, visiting Chamalières and taking part at a reception at Clermont-Ferrand. On Sept. 10th the party will dine and sleep at Châtel-Guyon, while the following two days will be occupied in a visit to Vichy. The approximate cost to the travellers will be 1100 francs, this figure being estimated to cover the cost of expenses for hotel accommodation and transport, between Pougues and Vichy, while a reduction of 50 per cent. can be secured on the French railways from the railway station on the frontier to the place of assembly, and from the place of disbandment back to the frontier. Full information will be supplied by Mme. Juppé-Blaise, Federation of Health Resorts of France, 1, Gordon-square, London, W.C.

AUSTRALIAN AND NEW ZEALAND MEDICAL ASSOCIATION IN ENGLAND.—The summer dinner of this Association will be held at the Trocadero Restaurant, Piccadilly, on Friday, June 15th, at 7.45 for 8 P.M. It will be preceded by a general meeting at 7.30 P.M., which all visitors and members are requested to attend, to elect office-bearers for the forthcoming year. Sir Anthony Bowlby will be the official guest of the Association and all medical visitors from Australia and New Zealand are invited to be present. The secretaries are Mr. E. T. C. Milligan and Mr. P. J. Jory, who may be addressed at 86, Harley-street, London, W. 1.

A HOSPITAL BENEFACTOR.—Mr. Dan Mason, who died suddenly at Biarritz on May 24th, founded and completely endowed the Chiswick General Hospital of 42 beds. It was established in 1911, and enlarged in the following year, and again in 1917. In addition, he made many benefactions to the West London Hospital at Hammersmith. He built a new nurses' home and was chiefly instrumental in providing new out-patients' and X ray departments, new operation theatres, a chapel, three new wards containing 39 beds, and a paying wing of 26 beds. He also founded the "Mason Samaritan Fund," which places 12 beds at St. Mary's Hospital, Broadstairs, at the disposal of the West London Hospital for child patients suffering from spinal complaints, surgical tuberculosis, &c., and provided the cost of maintaining the female accident ward of 14 beds, less contributions from patients. Mr. Mason was the founder and chairman of the Chiswick Polish Company. By his will he has given £5000 each to the pension funds of the West London and Chiswick Hospitals, and the residue of his estate is to be distributed among London hospitals and other charities at the discretion of his trustees.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

FRIDAY, June 15th.—8 P.M., OBSTETRICS AND GYNÆCOLOGY. Prof. A. Louise McIlroy: A Case of Dysmenorrhœa Due to Calcification of the Ovary. Mr. Clifford White: Vulval Metastases from Pelvic Growths. *Paper:* Prof. W. Stroganoff (Leningrad): Standard of Results in the Treatment of Eclampsia. An experiment in the treatment of eclampsia by telephone consultation. (Communicated by the hon. secretary.)

SATURDAY.—3 P.M. (at the Pharmacological Laboratory, Oxford), THERAPEUTICS. Annual General Meeting: Election of Officers and Council.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, June 12th.—5 P.M., Dr. Charles Bolton: The Interpretation of Gastric Symptoms. (Last Croonian Lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, June 11th, to SATURDAY, June 16th.—ROYAL EYE HOSPITAL, St. George's Circus, Southwark, S.E. Clinical demonstration by Mr. MacCallan on Mon., at 3 P.M.—ROYAL NORTHERN HOSPITAL, Holloway-road, N. Clinical demonstration by Mr. Lane-Roberts (gynæcology) on Mon., at 10 A.M.—HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W. Clinical demonstration by Dr. Anthony Feiling on Tues., at 2 P.M. The above are free.—CHILDREN'S CLINIC, Cosway-street, N.W., and other hospitals. Second week: Instruction in all branches of diseases of children.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.

MONDAY, June 11th.—1.30 P.M., Mr. R. J. Cann: Examination of the Nose.

WEDNESDAY.—1.30 P.M., Mr. N. MacKeith: Examination of the Ear.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.

TUESDAY, June 12th.—4 P.M., Dr. R. R. Trail: Visit to King Edward VII. Sanatorium, Midhurst.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY.

THURSDAY, June 14th.—5 P.M., Dr. P. Fildes: Principles of the Treatment of Tetanus with Antitoxin.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, June 12th.—3.15 P.M., Dr. W. R. Reynell: The Autonomic Nervous System, Its Forms and Functions.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, June 11th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. James Collier: Vascular Disease as it Affects the Central Nervous System.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Mr. Armour: The Surgical Aspects of Compression Paraplegia.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Mr. Just: Demonstration of Methods of Testing the Eighth Nerve (in O.P. Dept.).

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M. Dr. Symonds: Disseminated Sclerosis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

MONDAY, June 11th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M. Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

On Monday and Thursday, at 2.30 P.M., there will also be demonstrations of Medical and Surgical Cases by Dr. J. Browning Alexander and Mr. H. W. Carson respectively.

ANCOATS HOSPITAL, Mill-street, Manchester.

THURSDAY, June 14th.—4.15 P.M., Mr. Platt: Treatment of Fractures with Demonstrations.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

TUESDAY, June 12th.—3.30 P.M. (at the Jessop Hospital), Mr. King: Hints and Tips in Midwifery.

FRIDAY.—3.30 P.M. (at the Royal Hospital), Prof. Hall: Clinical Cases.

Appointments.

MILLS, G. Percival, M.B., M.S. Lond., F.R.C.S. Eng., has been appointed Hon. Surgeon to the Birmingham General Hospital.

COPE, V. Z., M.D., M.S. Lond., F.R.C.S. Eng., Surgeon in Charge of In-patients; and HANDFIELD-JONES, R.M., M.C., M.S. Lond., F.R.C.S. Eng., Surgeon in Charge of Out-patients, St. Mary's Hospital.

Vacancies.

For further information refer to the advertisement columns.

All Saints' Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, S.W.—Res. Sen. H.S. At rate of £200, also H.S. At rate of £150.

Birmingham General Hospital.—Asst. S. £50.

Birmingham and Midland Homœopathic Hospital and Dispensary.—Res. H.S. £150.

Brighton, Royal Alexandra Hospital for Sick Children.—H.S. At rate of £120.

Bristol General Hospital.—Hon. Clin. Assts.

Child Guidance Clinic.—Psychiatrist and Med. Director. £120; also Asst. Psychiatrist, £600.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Radiologist. 150 guineas.

Coventry, Coventry and Warwickshire Hospital.—Res. H.S., also Res. H.P. Each at rate of £125.

Doncaster Royal Infirmary.—3rd H.S. At rate of £150.

Dreadnought Hospital, Greenwich.—H.P. and H.S. At rate of £110.

Durham County Hospital.—Jun. H.S. At rate of £120.

Elizabeth Garrett Anderson Hospital, Euston-road.—H.P., Obst. Asst. Also 2 H.S.'s. Each at rate of £50.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—H.P. At rate of £150.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—Cas. Surg. O. At rate of £100.

Hellingley, Sussex, East Sussex County Mental Hospital.—Jun. Asst. M.O. £350.

Inverness, Northern Infirmary.—Jun. Med. Res. £100.

Ipswich, East Suffolk and Ipswich Hospital.—Two H.S.'s. Each at rate of £100.

Liverpool Sanatorium, Delamere Forest, Frodsham.—Asst. Med. Supt. £250.

Manchester Ancoats Hospital.—H.S. At rate of £100.

Manchester, Baguley Sanatorium.—Asst. M.O. £350.

Manchester City, Education Committee.—Asst. School M.O. £600.

Manchester, Crossley Maternity Hospital, Ancoats.—Res. M.O. At rate of £50.

Manchester, Prestwich County Mental Hospital.—Asst. M.O. £350.

Manchester Royal Eye Hospital.—Sen. and Jun. H.S.'s. £150 and £120 respectively.

Manchester, Salford Royal Hospital.—H.P. and H.S.'s. All at rate of £125.

Margate, Royal Sea Bathing Hospital.—Two H.S.'s. Each at rate of £100.

Miller General Hospital for South East London, Greenwich-road, S.E.—H.P. At rate of £125. Also H.S. At rate of £125.

Oldham Royal Infirmary.—3 H.S.'s. Each at rate of £175.

Poplar Hospital for Accidents, East India Dock-road, Poplar, E.—Sen. Res. O. £200.

Royal Chest Hospital, City-road, E.C.—Med. Reg. £50.

Royal College of Physicians of London and Royal College of Surgeons of England.—Streatfeild Research Scholarship in Med. and Surg. £250.

Royal Naval Medical Service.—Surg. Lieutenants. £453.

Royal Northern Hospital, Holloway, N.—H.S. At rate of £70.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. At rate of £100.

St. Mary's Hospital, W.—Asst. Director to Surgical Unit. £750. Also Asst. Pathological Chemist. £300.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Clin. Assts.

St. Peter's (Whitechapel) Hospital, 74, Vallance-road, E.—Deputy Res. Med. Supt. £600.

Shrewsbury, Berrington Hospital.—Res. M.O. £250.

Southampton, Royal South Hants and Southampton Hospital.—H.P. £130.

Southport General Infirmary.—Jun. H.S. £150.

South Shields, Ingham Infirmary.—Sen. and Jun. H.S.'s. £200 and £150 respectively.

University of London.—External Examinerships.

University of London, South Kensington, S.W.—Graham Scholarship in Pathology. £300.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Sen. Res. M.O. £250.

Willesden General Hospital, Gynæcological Out-Patient Dept.—Clin. Asst. Surgical Out-patient Dept. 2 Clin. Assts.

Windsor, King Edward VII. Hospital.—Sen. H.S. At rate of £120.

Wrexham and East Denbighshire War Memorial Hospital.—2 Res. H.S.'s. Each at rate of £100.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Wishaw (Lanarkshire), Scalloway (Zetland) and Beauly (Inverness-shire).

The Secretary of State for the Home Department gives notice of a vacancy for an Ophthalmic Specialist Medical Referee under the Workmen's Compensation Act for the Lanark District (Sheriffdom of Lanark). Applications should reach the Private Secretary, Scottish Office, Whitehall, London, not later than June 23rd.

Births, Marriages, and Deaths.

BIRTHS.

BILLING.—On May 29th, at Denholm, Chingford, the wife of Dr. E. Billing, of a daughter.

MARRIAGES.

BRAYFIELD—BEASLEY.—On May 26th, at St. Andrew's, Neasden-cum-Kingsbury, Felix Francis Brayfield, D.S.C., L.D.S., R.C.S. Eng., to Winnifred Mary Beasley, L.R.A.M., second daughter of the late H. R. Beasley, of Hornsey, and Mrs. Beasley, of Neasden.

DEATHS.

SHUTTLEWORTH.—On May 28th, at 36, Lambolle-road, Hampstead, George Edward Shuttleworth, M.D., M.R.C.S., Fellow of King's College, London, in his 87th year.

YOUNGER.—On June 2nd, at 2, Mecklenburgh-square, W.C., George Cuthbert Nelson Younger, M.R.C.S., L.R.C.P., son of the late E. G. Younger, M.D., and beloved husband of Lilian E. Younger (Née Abdy).

N.B.— A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE SURGERY OF YESTERDAY AND TO-MORROW.

Being an Address delivered at the Opening of the New Operating Theatres at Addenbrooke's Hospital, Cambridge.

BY SIR BERKELEY MOYNIHAN, BART.,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

IT is said that there are stars so far away from us that with light travelling at the rate of 187,000 miles a second, their inhabitants, if any, and if capable of far-distant vision, would now be watching the events upon this earth at the time of the Crucifixion. I wish that it were possible for a few minutes for us to be in a star so distant that we might be able to peep into a Leeds operating theatre and there to follow the day's work, 40 years ago. I choose the period of 40 years, for in 1888 I was house surgeon to Mayo Robson, who in activity of thought, variety of practice, and technical accomplishments was far advanced in the incubation period from which he soon emerged as one of the foremost surgeons of his day.

Let me try to describe what we did in those days. I fear you will be shocked.

An Operating Theatre Forty Years Ago.

The surgeon arrived, doffed his coat, lest he should soil it with blood or pus, rolled up his shirt-sleeves, and took down from a cupboard in the passage leading to the theatre an old coat, as a rule a frock-coat of antique design, which bore many marks of usage, and was stiff here, there, and everywhere with blood, of which layer after layer had dried into its very fabric. One, at least, of the coats was worn with a special pride, indeed with a certain jauntiness, for it had been inherited from a retiring member of the staff. The cuffs of the coat were rolled back a little, just above the wrists; and the hands were washed in a "tip-up" basin, which was never cleansed except in the ordinary domestic way. The hands, when clean in a social sense, were soaked in a solution of carbolic acid, whose strength varied with the resistance of the surgeon's skin to its irritating effects. We used a 1 per cent. solution: and even with this our hands were often numb by the end of the afternoon; and the sodden skin became afterwards very rough and harsh, and desquamated for several days.

The patient meanwhile had been wheeled into the theatre, placed on a flat wooden operation-table (I keep in my consulting-room that which McGill used for his prostatectomies, in memory of the fact that I helped him with his first case), and the anæsthetic was given. In Leeds we preferred ether, following the teaching of Mr. Pridgin Teale. The skin of the operation area had as a rule been prepared some hours before; it was washed with ordinary soap, shaved, and a "compress" soaked in a weak solution of carbolic acid was applied. When this dressing was removed on the operation-table, a further application of 1 in 40 carbolic acid was made, and towels wrung out of this solution were laid around the site of the wound now to be made. The instruments had been taken from the cupboard, whose shelves were lined with green baize, and placed in a tray of 1 in 20 carbolic acid, about half an hour before operation. Turkey sponges, cleansed and soaked in carbolic acid for days or weeks, were used, and when soiled were wrung out of boiled water and weak carbolic acid; about six sponges sufficed for an operation. For an abdominal operation we had flat Turkey sponges in addition. When all was ready the spray was turned on, and a fine mist of steam, odorous with carbolic acid, soon bathed all engaged in the operation. If the spray failed, as it sometimes would, a shudder ran round the theatre, and we gazed at each other in horror and deep apprehension as to the dire consequences of this unpardonable lapse on the part of the responsible dresser. In our mind's eye we could see the baffled germs, kept back so long by the antiseptic barrage, swooping down to the wound. Rubens, not even when he painted Saint Ignatius in the rite of exorcism, ever saw evil demons more clearly. In the case of a senior member of our staff, consternation was turned to respectful admiration at the extent and most decorative variety of his vocabulary of denunciation and colourful invective. I have always suspected one of our students, a great friend of mine, a stalwart colonial, of having now and again engineered the catastrophe, in order to learn something which might enrich his own vocabulary, in which, however, few of us were ever to discover any serious deficiency.

The house surgeon, who assisted generally, wore an old coat or a "blazer," whose long service had earned a rest: the dresser, who handed instruments and ligatures, was

content with the turned-back cuff. The ligatures were of catgut, rolled on to spools kept in boxes filled with carbolic oil and fixed to the kidney-shaped instrument tables. It was the duty of the operation porter to roll the catgut, delivered by the maker in small bottles, on to the spools.

As soon as the operation was complete, the whole area involved in it was washed, over and over again, with an antiseptic solution, that most commonly used being carbolic acid of strength between 1 in 40 and 1 in 100. Clean cases and infected cases were treated alike. Often the edges of the wound were held together, and the lotion forced into the wound with a Higginson's syringe, in the hope that the "cellular spaces" would be distended with the antiseptic. All wounds except the smallest were drained. A "radical cure" of hernia, for example, was treated by Mitchell Banks's method; the sac up to the external abdominal ring was removed. The hernia, that is to say, was converted from a complete rupture to a bubonocele. The wound before closure was wiped over with a 1 in 8 solution of carbolic acid in glycerine, and a drainage-tube was introduced. This exact method I saw practised nearly 20 years later by Lucas-Championnière (who explained that he had never varied the method since he had learned it from his master, Lister, in Edinburgh.) Bassini had not, in 1888, published his paper in which he first made it clear that the inguinal canal must be laid open and repair begun, not at the external, but at the internal ring. Over the closed wound iodoform was dusted and a dressing of carbolised gauze and salicylic silk padding was held in position by carbolised bandages.

There was one operation day in the week, Thursday. The senior of our four surgeons began at one o'clock; his list completed, the surgeons followed in order of seniority, Jessop, Atkinson (a Hey on his mother's side), McGill, and Mayo Robson. The time at which our firm could begin was regulated by the length of the lists of the seniors and by their punctuality, not always or often impeccable. I can still see Mayo Robson, arriving in the hope of an early start, but frustrated and delayed, becoming more and more impatient. He was even then the busiest member of the staff outside the hospital and had no time to waste. So in desperation, another day was demanded for his list, and one of the most startling innovations, bitterly opposed, of course, was inaugurated.

Abdominal Surgery.

Abdominal operations were things apart. No deliberate abdominal section was ever made in the ordinary theatres. Private wards were available, and special nurses; and the hour of 8 A.M. was consecrated to the performance of such very critical operations. It was the prerogative of the resident surgical officer to help with every one.

The year 1888 was an eventful one. No case of appendicitis was operated upon, though our records show one case of "perforation of the vermiform appendix" treated by operation in 1887. In 1888 one case of "perforating ulcer of the stomach" was operated upon with a fatal result; and one case of gastro-jejunostony for carcinoma of the pylorus also failed to recover. In all, 45 abdominal operations, including "explorations," were performed, with 12 deaths. Of the 45 cases, 14 were examples of ovarian cyst. The first nine cases of cholecystotomy were performed, with two deaths.

The cases of acute intestinal obstruction, transferred, after due delay naturally, from the medical wards to which in the first instance they were invariably admitted, exhibited a veritable martyrology. Any escape from the dread of the cases was worth consideration, and I am sure we saw little humour in the suggestion made by Jonathan Hutchinson that the victim of strangulated intestines might fortunately experience a disentanglement of his ensnared bowel if, while held by the arms and legs by stalwart policemen, his body, face downwards or inverted, was heartily shaken from side to side, or submitted to vigorous abdominal taxis combined with copious enemata. Hutchinson in 1890 admitted that this was a "troublesome and somewhat undignified procedure," but was confident that if it could be shown to be effectual "no conscientious surgeon will allow himself to neglect it because it is disagreeable." As a solace to those who might regret the loss of a case not treated by operation, he asserted that during 20 years of surgeoncy at the London Hospital he had never, so far as memory served, encountered a case in which the post-mortem upon a case of intestinal obstruction made him regret that he had not opened the abdomen. If one of the most distinguished members of our profession, who was then President of the Royal College of Surgeons, could say this, what criticisms as to ill-conceived and reckless adventure might not the pioneer in surgery expect from the physician or pathologist? What courage and what indifference to criticism must the surgeon then have shown. Mikulicz told me, in 1903, that he had operated upon 35 cases of perforated gastric ulcer with 34 deaths. (I have never found the published record of this.) But, as I used to tell my students, there was another way of looking at th story. Mikulicz had operated upon 35 cases, with or recovery. One life was saved, not a large number sacrifice

Coats and Gloves.

I well remember the first coat ever made for speci wear in the operating theatre. Mayo Robson designed i The material was a soft tweed, of rough surface, and light blue-grey in colour; it reached the knees, and i stand-up collar came near to the chin. It was worn f years, and I clearly remember that on one occasion, certainl it was cleaned. When I became resident surgical office in 1890, I introduced white washable coats; and I can reca my shyness at entering the theatre with Mr. W. H. Brow both of us in spotless white, and the titter which develope into a guffaw at our ridiculous appearance. Rubb gloves did not come until later, and I believe that I was t first surgeon in Europe to wear them. They were introduce into surgery by Halsted, of Baltimore. I had been struc by Halsted's writings, and in my youthful enthusiasm ar gratitude I had written to him inquiring about some poi in connexion with hernia. He was a good and most co siderate and helpful correspondent; and soon after h introduction of the rubber glove he sent me six pairs, and wore them for months, puncture or no puncture, and enjoye the mocking hilarity of my colleagues and the students.

The complete change of clothes, white shoes, trouser coats, sleeves, cap, and mask, did not begin with us unt May, 1903. The students called me then the "pylor pierrot." It is astonishing to learn that even to-day t change of clothes for work in the theatre is not universa For, in the first place, it is quite a simple experiment demonstrate, by soiling clothes with easily recognisab organisms (the bacillus prodigiosus, for example) that germ are cast from them to all parts of the theatre. Some these may be harmful to the wound; and it is better to ke them away. And, in the second place, the comfort of t surgeon is something; and the comfort of a change undeniable. The reek of ether in the garments of the theat is sometimes very unpleasant to patients or friends se later in the day.

Equipment and Technique.

The theatre itself has changed beyond recognitio Forty years ago the benches in our theatre were of wooc the windows had heavy sills, the roof had beams across it the instrument cupboard was of oak, with lined wood shelves, the floor was covered with oilcloth, there was an ope fireplace, the chairs were of the ordinary kitchen type one door opened into a corridor, another on to the landin at the top of the staircase along which everyone passed the wards. A spray in the theatre was very necessar Leonard Hill has lately shown the surprising effects produce on the germ content of the atmosphere by spraying it wi an antiseptic.

The work done in the theatre was of course quite differe from that seen there to-day. A comparison of our operatio lists 40 years ago, with those of the present time, are fu of interest. Tumours were removed, deformities repaire defects made good, sinuses leading down to tuberculo glands or necrosed bone were dilated and scrape "Bigelow's dilator" was an instrument required for eve operation list and lay beside Volkmann's spoon. M Jessop used to say that the change wrought by Lister surgery was that surgeons learnt to wash their han before operating rather than afterwards; that, in shor an operation was a clean thing, not a dirty thing. Surger when made safe by Lister, ceased to be merely remedia and became the most powerful instrument for research in the diseases of man ever placed in our hands. It is almo impossible to convey to a young surgeon of to-day t bewilderment in the minds of older surgeons when fir they were confronted by conditions within the abdom which no text-book of medicine or pathology could explai When McGill began his work on prostatectomy the patie was placed in the Trendelenburg position (a position intr duced into surgery for operations upon the bladder) and t prostrate nibbled away or enucleated under the eye of t surgeon. This old method has been rediscovered at t Mayo Clinic and by Thomson-Walker; but such lapses professional memories, followed by renewal of forgott methods, are not unusual. The text-books of the time to us little or nothing of variations in the form of the prosta and the different mechanical effects thereby produce In the abdomen the confusion was far worse. I recall a occasion at the meeting of the Leeds and West Ridi Medico-Chirurgical Society when Mayo Robson spoke having introduced his finger into the common bile duc A pathologist made this an opportunity for derision at t absurd statements by surgeons, which he said were becomi alarmingly frequent. He pointed out that the comm duct could comfortably contain a knitting-needle, that t presence of a human finger within the duct implied eith an attenuation of the digit, or an expansion of the duc

ith neither of which had his observations made him amiliar.

The Debt of Medicine to Surgery.

During the year of my house surgeoncy the hybrid word ppendicitis was not mentioned. That the appendix was ttacked by inflammation and gangrene, that it might suffer erforation, and be the cause of a generalised peritonitis, ad been recognised by Wilks and Moxon, and made clear y R. Fitz, of Boston, in 1888. Fitz it was who first recog-ised and described acute pancreatitis. For our modern nowledge of abdominal diseases, their symptoms, their lliances, and the modes of operative treatment best suited) them, we are indebted almost wholly to the surgeons. have before suggested a comparison between the knowledge isplayed in the first edition of Fagge's Medicine, and our nowledge of to-day, to show the debt which medicine owes) surgery. Surgery then, as created by Lister, is not only remedial measure, safer beyond all calculation than it as before his time, but it is a method, the best indeed of l methods, of inquiry into the symptoms, the origin, lation, and progress, and the treatment of intra-abdominal sorders. Surgery has had, however, to fight too much one. The physician in many cases, happily not in all, ad seemed to lose interest as soon as the surgeon takes harge of a case, with the unfortunate result that a spirit antagonism as between medical and surgical treatment as been allowed to creep in, and to embitter relationships etween the practitioners of each method. This is not only olish, but wrong. Our business is to understand, to ntrol, and where possible to alleviate or remove diseases om patients who suffer. We are all, therefore, working the same end, and we shall work better if we work together. he physiologist, too, has seemed to stand aloof. As Dr. G. Douglas and I pointed out last autumn, almost multaneously, human physiology has been too much glected. Research upon animals, for some quite inex-icable reason, has been put in the foreground. For this isdirection of effort, responsibility, or perhaps I should y, blame, in my judgment attaches both to the Medical esearch Council, which in some degree inspires and finances research work," unaware, or indifferent to the value of search in the wards or operating theatres, and to the Royal ciety which now gives its Fellowship as a reward almost clusively to those who spend their sheltered lives in the oratory and are ignorant of clinical research ; neither body well-advised. To-day every surgeon realises how much depends for an insight into the maladies afflicting his tients, and for his power of control of them, upon the thologist and his co-workers. They are able to tell m what things have happened, what changes have already ken place in tissues, secretions, excretions, &c. ; and from is much is learnt to guide the principles or the details of eatment. I think physiologists, by a study of the normal, d the almost normal, would surely give us help in dis-vering far earlier changes, and would enable us to prevent me, at least, of those late and terminal conditions with hich to-day we are far too much involved. If preventive edicine is to-day in the forefront of our minds, is there t preventive surgery also ? And if there is, will a study fully developed diseases, such as the surgeon meets in spital, be the best means of advancing our intimacy th it ? Can we expect to learn embryology by the study fossils ?

The Pathology of the Living.

The next step to be taken in hospital administration ll, I hope, involve the appointment of general practitioners o upon the staff, and the provision of beds where early ses can be admitted for observation and inquiry. Here an almost virgin field for investigation by experts, and in s matter the general practitioner, and not the consultant, the expert.

When I was a house surgeon our knowledge of the nptoms and results of disease were based upon descriptions efly written by physicians attached to our teaching hos-als, and by pathologists who examined the bodies of ose dead, very often at long last, of their diseases. Patients not, and were not then, admitted to hospital unless their eases were in full course, and gravely threatening life health. What could the physician to a teaching hospital ow of inaugural symptoms, and what opportunities sented themselves to a pathologist for recognising early uctural changes ? When the adventures of the surgeon ced at his disposal earlier material for a study of morbid nges than those which had caused death, his observations re often derided and denied by post-mortem pathologists. support of our claim to a knowledge of far greater value n that derived from autopsies, I spoke of the " pathology the living." And when discussions arose as to the urrence or frequency of malignant degeneration in a onic gastric ulcer, I suggested that a " histology of the ng " was needed to settle the question. I have known th occur from " recurrence " of carcinoma in the liver a patient whose stomach had been removed for what the pathologist refused to accept as " cancer." Happily the process of tissue culture may help us here ; and we may perhaps recognise a different behaviour in many respects when a simple is compared with a malignant cell, as each is minutely observed undergoing growth and multiplication.

Alliance of Surgery with the Sciences.

The plea I make to-day is for all sciences to be brought into an even closer alliance with surgery. The craft of surgery has reached something near the goal. If operations have to be practised in the future, it is not possible to imagine any considerable improvement upon the methods and results of to-day, as exemplified in the hands of the great masters. Other methods of treatment may come to the fore, and much may be expected from prevention ; but expert craftsmanship with a perfect technique can do little more to improve our work. The art of surgery has outrun its science. The corollary is obvious. It is that the ancillary sciences must help surgery more than they are now doing. Chemists, physicists, but especially and immediately physiologists, must come closer to us, and be encouraged to find in routine work upon human beings who show a minor departure from standards of health, some explanation of this deviation and some methods of averting or arresting the morbid process. There are hosts of questions that the surgeon asks, and until the physiologist learns, by daily work in the wards and in the theatres, what those questions are, it is not to be expected that he will make the effort needed to answer them, or even perhaps realise that an answer is urgently demanded. Physiology needs a new orientation ; its interests are now too largely centred on problems of secondary interest to mankind. I should like to see a physiologist also added to the staff of every teaching hospital.

Now let us suppose that a surgeon who had ceased to practise 40 years ago, who had seen and heard nothing of surgery in the meantime, could be brought back to an operating theatre to-day, and could stay with us for a day's work. What would be his impressions ? I fear that he, too, would be shocked. He would discover at once that the architecture and equipment of theatres had been radically altered. He would find the apparel and behaviour of surgeons, nurses, and spectators changed to a degree that would at first seem ludicrous. He would see the old operations, upon which he embarked with anxiety and alarm, performed with a degree of confident ease and their issues regarded with a degree of certainty that would astound him. He would watch operations, the very names of which might be meaningless to him, and the very thought of which would strike him with acute misgiving and dismay. He would remember that in his day a man who practised ovariotomy was held, by responsible and sober-minded people of his own profession, to have earned an indictment for manslaughter. He would realise that the surgeon was on terms of almost indecent intimacy with the brain, the heart, lungs, and abdominal viscera ; and this knowledge of the diseases of these organs, which every word and action revealed, would leave our honoured visitor utterly bewildered and incredulous. You will complete the picture for yourselves. I ask you only to remember that it was the labour of one who was physiologist as well as surgeon who made all this possible ; and that if we are to carry his work still further and perhaps complete it, it can only be by conjunction in effort of physiologist and surgeon in the wards and operating theatres to-day.

WORLD LEAGUE FOR SEXUAL REFORM.

Dr. Norman Haire asks us to announce the foundation of a World League for Sexual Reform (W.L.S.R.), designed to make the results of scientific sexual research of practical service to mankind. Its chief object is to encourage the development of sexual sociology and sexual ethic based on biology and psychology rather than, as in the past, on theology. The first World Congress of this league is to be held in Copenhagen from July 1st to 4th, the place of meeting being the Studentenforeningen, Vestre Boulevard 6. At the inaugural session, 10 A.M. on Sunday, Dr. Hirschfeld (Berlin) will lecture on Sexual Reform, to be followed by a debate in the afternoon. On Monday Mrs. Dora Russell (London) will lecture on Sexual Education. On Tuesday Dr. Leunbach (Copenhagen) will lecture on Birth Control, and on Wednesday Prof. Pasche-Oserski (Kieff) will lecture on Sex and Criminal Law. Anyone wishing to join the League, or to participate in the Congress, should apply to Dr. Leunbach, Stockholmsgade 39, Copenhagen, Denmark.

THE Health Service Bureau of the Wesleyan and General Assurance Society writes to point out that all distributions of the pamphlets described in our last issue are made entirely free of charge.

PRACTICAL AND VIVA VOCE EXAMINATIONS.

DURING this part of a summer session medical students at all stages are facing examiners with feelings of anxiety which might have been less acute if they had devoted more attention to the pattern of the practical and viva voce examinations before them. In the course of a leaflet on the duties of examiners issued by one of our largest universities, the general scope of such examinations is well defined. A practical examination is designed to be a test of practical experience, skill, and accuracy; a viva voce should be a guide to the range and precision of the candidates' knowledge. If this distinction were borne in mind by students and their teachers, rehearsals appropriate for each ordeal might be planned. Before a practical examination, set tasks could be deliberately and carefully performed in a given time, whether in a laboratory or at the bed-side. This task should not be hurried. The work set always takes up less time than is allotted if things go well; even when accidents occur, there is usually ample margin. Moreover, to quote from the recommendations referred to above, such exercises are set "in the carrying-out of which one mistake will not lead to the total loss of definite results." Before viva voce examinations, preparation should be sought in the form of "rags" during which a rapid fire of quite unconnected questions is directed to one student. Systematic interrogation of each member of a class in turn does not develop the quick reaction time which is essential for success. Candidates who complain that the questions asked them at viva voce examinations become progressively more difficult can take comfort from the knowledge that this is not exasperation, but deliberate instructed policy, for "examiners are reminded that in order to make it more easy for candidates to overcome the nervousness from which they are likely to suffer, it is advisable that the first questions put to them should be of a comparatively simple character." The nervousness is not likely to be all on one side, since the examiner who reads his instructions will find that his powers are limited and his duties arduous. Graduates who are appointed to this high office before the memory of their ordeals on the other side of the table has had time to fade are nearly always surprised by the low level of the answers at ordinary pass examinations. They also learn that a sympathetic attitude towards candidates is required if the pass-list is to be issued with a reasonable proportion of names above the line, and that their first and most important duty is to cultivate and maintain this attitude.

IMPROVEMENT OF TRANSPORT BY AMBULANCE.

THE keen discomfort, sometimes amounting to acute pain, caused to victims of accident or acute illness by the jolting of a badly sprung ambulance is seldom the subject of definite complaint. The sufferer has to undergo still more strange and perhaps more distressing experiences in the hospital or nursing home, and his gratitude for the prompt attention and swift removal is stronger than his memory of the uncomfortable journey. Special inquiry on the part of the practitioner, however, will occasionally elicit the fact that in spite of most careful handling by the attendants the journey was a nightmare. This was the experience of a patient known to us who after a perforation of the intestinal tract found a short drive through a well-paved town in an ambulance much less tolerable than a much longer period in a smooth-running private car on country roads. Squeaks and rattles are disturbing, but not serious inconveniences; more important are defective springing and shock-absorption, but it was the vibration of an old engine and the jerking due to a fierce clutch which caused most distress in the particular case brought before our notice. The ambulances under the control of the Order of St. John and the British Red Cross Society are for the most part kept in good repair. According to the report for the last quarter of the Home Service and Ambulance Committee complaints are rare, and the committee note with satisfaction the increased attention given by stations to the care of their ambulances. They point out, however, that many of the ambulances are housed at commercial garages and driven by hired drivers. Arrangements are made for cleaning and ordinary attention, but the average garage proprietor is not likely to be on the watch for the minor defects that develop in motor vehicles and may distress or even harm the patient. That the attendants whose duty it is to travel with the patients, do not always observe the development of jolts and rattles and discover their origin is evident from the condition of many of the ambulances when they are returned to headquarters at the end of their service. The first and most frequent neglect is that of oiling and greasing the chassis, especially in the less accessible parts. Especial attention is drawn to the neglect of the oilers on the spring perches, particularly those at the rear. The springs themselves are sometimes left too long without being re-greased. Back springs are allowed to settle, bringing the tail of the body down; these should be properly set up. Improvement in this respect can sometimes be achieved by fitting longer perches, which are effective in reducing the body sway and also, when the load is heavy, in preventing the bumping of the wings against the tyres. In a number of ambulances returned to headquarters the commutator is in a dirty state, the coil system has been exposed to leakage of water through defective joints in the dash, and the bodywork has been neglected in that screws of latches and fittings of windows, doors, and seats have been allowed to get slack. It would be unfair if this statement were taken to imply that the majority of ambulances are in an unsatisfactory condition. Tributes to the punctuality and care shown by the voluntary workers are constantly being received and are well deserved. At the end of March, 1928, there were 302 of the committee's ambulances in the country, as well as 62 affiliated stations; during the last quarter these 364 ambulances carried 648,142 cases. It is in view of the increasing activity of this branch of first-aid work that attention has been called to the need of improving the standard of comfort in some of the older vehicles and to maintaining it in the newer ones. The committee offer many hints directed to this end, of which the most useful is the information that air mattresses can be obtained to fit standard road stretchers. The addition of such a mattress to the equipment will make long journeys tolerable even in an ambulance which has seen its best days. Local detachments will be well advised to provide themselves with such a useful and inexpensive means of neutralising the shocks of the road.

A MEDICAL SOLDIER.

THE death of Major-General Leonard Wood last year removed a man of great achievement, who will be remembered as one of the most remarkable Americans of our time. An address by Major-General C. P. Summerall, of the United States Army,[1] gives a good idea of his career. The son of a village doctor in New Hampshire, he was a man of outdoor sports, but also an omnivorous reader. He took up the study of medicine, graduated in 1884, and passed, second of 59, into the U.S. Army medical service. Reporting in Arizona on July 2nd, 1885, he persuaded Captain Lawton to take him next day on an expedition. It lasted 21 months, and when the last company commander left through exposure and fatigue, Wood volunteered for the duty, and at the end, received the Medal of Honor for distinguished conduct. On 1898 he became colonel of the Rough Riders in Cuba; six weeks later his regiment drove out the Spaniards, and he spent the night dressing the wounds of 30 of his men. A fortnight afterwards he was promoted brigadier-general, and was made governor of Santiago, and such was his success as administrator that in due course he was appointed military governor of Cuba. He thought yellow fever might be due to a mosquito, and cordially supported Read and his colleagues in their work. His initiative, says General Summerall, made the Panama Canal possible, and Lord Cromer described his administration as governor-general of the Philippine Islands as the greatest colonial work of the century. For four years he served as Chief of the General Staff of the United States Army—a prophet of preparedness—and in 1913 he started the officers' training camps, which furnished 100,000 officers in the World War. His advice to others, as to himself, was "Always volunteer, no matter how dangerous or unpromising the task; you are likely to discover opportunity. Do things, don't talk about them." No soldier could outwall him, none had more ceaseless energy, he was never too busy to be courteous and kind to juniors, and secured the devotion of those who served with him. That his name may be kept continuously in the minds of United States Army officers, it has been decided that the military station near Washington shall, in future, be called Fort Leonard Wood.

CARBON MONOXIDE GAS POISONING.

WE regret that Prof. Hamilton Hartridge's paper on this subject, appearing on p. 1137 of THE LANCET of last week, was published without the corrections made by the author in Table II. the words "in actual hæmoglobin" should read "found in hæmoglobin"; in section 8 the symptoms of poisoning by exhaust gas ought to be given as "dullness, dizziness, sickness, and weakness of the limbs" (not bowels) whilst in section 10 the remedies mentioned should be "oxygen in cylinders, or, better, oxygen with 5 per cent. (not 50 per cent.) carbon dioxide." The publication whose name is given in reference 1 is issued by the United States Bureau of Mines.

[1] Military Surgeon, April, p. 526.

BROMLEY (KENT) COTTAGE HOSPITAL.—A Diamond Jubilee Fund of £12,000 is being raised for extensions and improvements. At present the operating theatre can be approached only through the surgery and accident ward.

Croonian Lectures

ON THE

INTERPRETATION OF GASTRIC SYMPTOMS.

Delivered before the Royal College of Physicians of London

BY CHARLES BOLTON, C.B.E., M.D., D.SC. LOND., F.R.C.P. LOND., F.R.S.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE II.

(Delivered on June 7th.)

ANALYSIS OF CASES OF PAIN.

(Continued from p. 1168.)

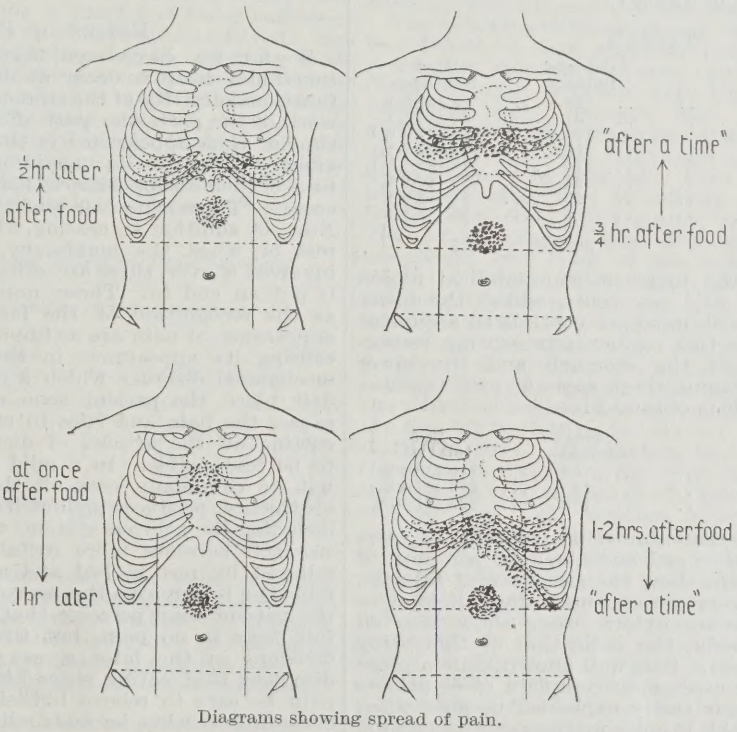
I HAVE already dealt with 715 cases of my series, who suffered from pain in isolated areas, and divided them into three groups, pyloric, cardiac, and œsophageal according to the position of the pain and its time of onset after food.

The remaining 294 cases of the series show multiple areas of pain, 261 of whom complained of pain in all possible combinations of the local areas already considered. The remaining 33 cases cannot be shortly classified but three types may be mentioned. Diffuse pain affected the ribs at both sides of the chest or more commonly the left only, and, speaking generally, the sixth rib separates this region into two parts, an infra-mammary in which chiefly early and irregular pain occurs, and the ribs below in which the pain is more likely to be late in appearance. The pain may take the form of a longitudinal line passing through the nipple and the ninth costal cartilage. Pain occurred in the sternum and along one or both costal margins and might also affect the central line. It would take too long to give all the figures relating to the analysis of these cases, so that the brief statement must suffice, that a comparison of their time relations as to the taking of food with those already described leaves no doubt whatever that the same interpretation may be given to the position of the pain and its time of onset whether single or multiple areas are concerned. When *all parts of the gastric apparatus are simultaneously affected* it is very difficult to say whether the disorders are independent of or related to each other in any way. There are, however, two circumstances which are worthy of notice.

1. The pain is usually described as *commencing at the same time* in each position. When the pains commence at the same period of digestion they show the characteristics of pyloric, or cardiac, or œsophageal pain just the same as in the case of the single areas, and it is therefore only reasonable to suppose that the same interpretation may be given to them. In 89 cases in which œsophageal pain was combined with that due to the pylorus or body, 50 per cent. of combined œsophageal and pyloric cases complained of late pain, and we must therefore assume that in these cases the œsophagus is affected by a backward effect from the pylorus, because primary œsophageal pain should occur early. A certain number of examples of cardiac pain occur late and œsophageal pain when combined with these also occurs late. So that it appears that either the pylorus or the body produce backward effects upon the œsophagus. On the other hand, when the pain occurs early or irregularly it indicates excessive irritability of the stomach either as an advanced pyloric manifestation or as a primary nervous irritability affecting all parts simultaneously.

2. The pain may be described as spreading *upwards* or *downwards* during digestion. Forty cases of this kind have been analysed. The spread upwards seems to show that the disorder may begin in the pylorus and secondarily affect the body of the stomach and the œsophagus by a backward effect; or in the body and secondarily affect the œsophagus. The pain may spread from any part, and the interval between the two pains varies from half an hour or so up to two or three hours, but most often the statements made are "after a time" or "later on"—for example, local pain in the upper sterno-umbilical region one hour after food followed in half an hour by a band of pain across the lower sternum, and so on. The pain may be described as spreading downwards in from a few seconds to half to one hour. It may spread from the sternum to the abdomen or down the costal margins (Fig. 1). Each mechanism is upset in turn, a general irritability of the stomach or œsophagus being present—for example, in the lower sternum half an hour after food, followed in half an hour by pain in the middle sterno-umbilical area. A rapid spread from above down denotes considerable nervous irritability, as, for example, in a neurotic patient who complained of a sore feeling in the whole of the sternum at once after food, followed by pain in the middle sterno-umbilical region which passed down on each side of the umbilicus, and ended in general colic and diarrhœa. The cases of combined pain, therefore, appear to indicate that a primary affection of the pylorus commonly produces backward effects through the body of the stomach upon the œsophagus, and similarly a primary cardiac affection produces effects upon the œsophagus. Also that all the parts may be affected together early or

FIG. 1.



Diagrams showing spread of pain.

irregularly or successively as they are brought into action owing to a general nervous irritability.

If this is the case the probability is that the same kind of process is really going on in the cases with isolated areas of pain, the irritability of the other parts not being sufficiently pronounced to cause actual pain. A study of the sensation of fullness or distension favours this hypothesis.

Sensation of Fullness.

The sensation of fullness is important, because it signifies a disorder of the body of the stomach, but it is not so valuable as referred pain in this respect, since it may be voluntarily produced by air-swallowing. This effect must, however, not be over exaggerated, because it chiefly occurs to any degree in the neurotic subject and is only seen in a certain number of such patients. It is certainly not of sufficient frequency to materially diminish the value of fullness as a symptom. Another disadvantage is the difficulty of clearly distinguishing this symptom from general abdominal fullness. In a series of 664 cases of pain, 523 complained of fullness. Of the 664 cases, 473 were instances of pain in a localised position, of which 363 showed the symptom of fullness in addition; and 191 of pain in combined areas of which 160 exhibited fullness. The cases of localised pain alone concern us at present. They are as shown in Table I.

TABLE I.

Region.	Cases of fullness.	In a total of—
Upper sternal	22	44 (50%)
Lower „	37	66 (56%)
Upper st.-umbil.	125	143 (87·4%)
Middle „	86	104 (82·7%)
Lower „	40	48 (83·3%)
Right 9 c.c.	25	31 (80·6%)
Left 9 c.c.	19	25 (76%)
Right and left 9 c.c.	9	12 (75%)
	363	473

The fact that the upper sterno-umbilical region shows fullness in 87·4 per cent., whilst the lower sternal only shows it in 56 per cent., is an argument in favour of these two regions representing respectively the body of the stomach and the lower œsophagus. Combining these areas of pain together the following result is obtained :—

Region.	Cases of fullness.	In a total of—
Œsophagus	59	110 (53·6%)
Cardiac end	125	143 (87·4%)
Pyloric „	179	220 (81·3)%

Thus it appears that almost 90 per cent. of cases of pain in the cardiac end and about 80 per cent. of cases of pyloric pain show the sensation of fullness. Allowing for exaggeration and inaccuracy, it is quite clear that very many pyloric cases show also an affection of the body, the indication of this being not pain but fullness. It is well known that in place of fullness pyloric cases may complain of emptiness and hunger. This is easily explained because when the pylorus is irritable it holds up the gastric contents, but the actual sensation produced depends upon the volume of contents remaining in the stomach. When the pylorus shows its irritability late or the stomach empties initially quickly and only a very little remains in the stomach, the feeling produced by the body is an empty feeling similar to that due to hunger. Thus the body of the stomach is usually affected when the pylorus is irritable, but produces two opposite feelings—a pain associated with fullness if a fair amount of material is present, or a pain associated with hunger sensations if very little remains in the stomach—in other words, a hunger pain. The œsophagus is associated with fullness in about half the cases, showing that the body of the stomach is also affected and the cause of the œsophageal symptoms.

It is also certain that many of such cases who feel symptoms late during digestion are secondary to pyloric irritability, for, as we shall see presently, they are liable to show acid regurgitation late during digestion, which is a pyloric symptom. Now it must be quite clearly understood that absence of pyloric relaxation, although it produces fullness or pain in the body and sour eructations with œsophageal symptoms, is not a cause of pyloric pain. It is only when the pylorus and adjacent part of the vestibule become spasmodic that pain results.

The following clinical types of pyloric irritability may therefore be recognised. (1) Pyloric pain with hunger sensations—hunger pain. (2) Pyloric pain with a sensation of fullness, with or without cardiac pain. (3) Fullness or pain in the body of the stomach without pyloric pain occurring at all. Acid eructations and œsophageal symptoms may result in all three cases. In the first, when hypersecretion is present, and in the second and third from regurgitation of the acid contents of the stomach. The third condition can only be diagnosed if a fractional test-meal shows failure in the neutralisation process and acid eructations occur late during digestion.

There can be no doubt that the most important type of dyspepsia is this pyloric type, due to pyloric irritability and its backward effects upon the cardiac end of the stomach and the œsophagus. A second type appears to affect the body of the stomach primarily with secondary effects upon the œsophagus. A third type affects the œsophagus only.

RELIEF OF PAIN.

So far we have seen that these symptoms of functional disorder occur at different phases in the functional activity of the stomach and cease when the work of the particular part affected is finished. The time of their appearance is that at which the part affected displays its maximum activity, and the time of their disappearance that at which this activity ceases. There is no pain when the stomach is empty. Now, in addition to ceasing when the stomach is at rest or when the maximum activity of the part involved is over, there are other ways in which pain is put an end to. These must now be considered as the recognition of the factors causing the disappearance of pain are as important as that of those causing its appearance in the explanation of the mechanical disorder which gives rise to it. In the first place, the patient soon realises that his food causes the pain and tries to reduce the stimulus by cutting off the articles of diet, which he considers to be responsible. In a mild case he may succeed, but he commonly cuts off the wrong food or, by abstinence, produces malnutrition of the whole body including the nervous system, with the result that his stomach becomes more irritable, and can only be relieved by rest in bed and a graduated diet with remedies to improve the nervous system. Secondly, the patient may perceive that when the stomach is full there is no pain, but that as it empties pain develops in the later stages; in other words, he discovers that eating stops his pain. When he has pain he eats to relieve himself and selects his diet according to what he finds relieves him best and for the longest time. It is quite plain that in this case the patient is bringing into play some automatic mechanism which counteracts the disorder causing the pain. Thirdly, relieving the stomach partially or completely of its contents temporarily or permanently puts an end to the pain. I refer to the two common motor disturbances which of themselves constitute symptoms of dyspepsia—namely, eructation and vomiting—both of which acts are also employed by the patient to relieve his symptoms. We have, therefore, to consider the questions of the relief of pain by food, and by eructation and by vomiting.

Relief by Food.

It has been a matter of common knowledge, probably from the earliest times, that the pain of dyspepsia is very frequently relieved by food. It may be completely relieved for a definite time or only partially relieved; it may disappear temporarily during the eating of the meal to return again shortly, or it may

be relieved on some occasions and not on others. It seems, therefore, that this common occurrence of the relief of pain is quite as definite a link in the chain of events as that of pain itself.

In this series there are 324 cases of isolated pain, of whom 190 were completely relieved of pain by food, 24 partially, 27 temporarily, and 65 unrelieved; 18 cases were sometimes relieved and sometimes not. The distribution of the 190 cases of *complete relief by food* is given in Table II.

TABLE II.

Region.	Cases.	With complete relief by food in—
Upper sternal	31	8 (25·8%)
Lower sternal	49	22 (44·8%)
Upper st.-umbilical	105	53 (50·4%)
Middle st.-umbilical	91	67 (73·6%)
Lower st.-umbilical	48	40 (83·3%)
	324	190

The highest percentage of cases in which relief s obtained by food occurs in those showing pain n the pyloric region (middle and lower sterno-mbilical areas); about half the cases showing pain n the body of the stomach and the lower œsophagus upper sterno-umbilical and lower sternal), which are imilar as regards the onset of pain, are afforded elief by food; and only a quarter of those suffering rom pain in the upper œsophagus are so relieved. So hat one of the factors influencing the relief by food s the part of the apparatus involved and therefore he particular function which is upset. On analysing he cases as regards the time of onset of pain, the nteresting fact is brought to light that, in all the egions involved, the cases in which pain comes on ate during the digestive process are those which are hiefly relieved of their pain by food. The result s given in Table III.

œsophageal cases, so that it is probable that any of the latter cases, in which pain occurs late, tained relief by food because they are secondary the pyloric end of the stomach. When we consider *partial or temporary relief of pain by food*, of which there are 51 cases, it appears that a greater relative proportion of cases with early pain are so relieved that when the relief is complete and especially those affecting the body of the stomach and the œsophagus. The analysis is given in Table IV.

A consideration of the 65 cases in whom the pain is *unrelieved by food* shows that they are chiefly the subjects of early and irregular pain. The analysis is shown in Table V.

The *irregular type of pain* is relieved at some times and not at others, for out of 18 cases of this kind of relief 14 were examples of the irregular type of pain.

The following deductions may be made. Pain may be relieved by food whatever part of the apparatus is affected and at whatever time the pain occurs. Complete relief is much more likely to be afforded when the pain appears late, whatever part is affected, but of all parts pyloric pain and its secondary consequences on the body and œsophagus are the most likely to be relieved. Pain occurring early or irregularly after food is unlikely to be relieved by food, or if so the relief is mostly temporary or partial. This is, of course, seen more particularly in the œsophagus and body of the stomach. Late pain, which is unrelieved by food or only partially or temporarily, means that the pain usually comes on late after a meal, but once started remains constantly present for the whole day. Early and irregular pain is characteristic of nervous irritability of the stomach, so that the more irritable this organ is rendered by the unstable condition of the central nervous system the less likely it is to be relieved of its pain by the taking of food. The factors to be reckoned with, therefore, in respect of the relief of pain by food are the type of case as regards the part of the apparatus affected and the function disordered, and the condition of the central nervous system as regards irritability. The explanation of these facts is clear when we consider how the pain is likely to be relieved.

It seems reasonable to assume that, if we are right in supposing that an overaction of the neuro-muscular mechanism is the cause of gastric pain at various stages of digestion, a cessation of this overaction relieves the pain. We have seen that such a mechanism for inhibiting the muscular movements exists and is brought into play in the normal filling of the stomach. This normal inhibitory mechanism must also be called into action in the condition of irritability of the stomach, but with varying degrees of success, according to the ability of the muscle-fibre to respond normally to the call. Neither can one expect this to be accomplished unless the normal balance between the extrinsic motor and inhibitory nerves is correctly adjusted. This is unlikely to be the case when the central nervous system is irritable. So that primary cardiac and œsophageal cases in which such irritability is the most common are less likely to be relieved by food than pyloric cases. The later the pain comes on the less irritable is the neuro-muscular mechanism and the better it responds by a lengthening reaction to the introduction of food, so that on the whole the pyloric type of case is more easily relieved. Nevertheless, pain coming on in half an hour after food is not uncommonly relieved, and pain which begins almost at once after food may be partially or temporarily relieved by the act of

filling the stomach. In other words, whilst eating his meal the patient is usually free from pain, which comes on again some short time after the meal is ended. This is due to the receptive relaxation of the stomach on swallowing through the vagus. The same remarks apply to those cases of late pain, in which the nervous irritability has become so excessive that the pain has commenced to appear early and lasts constantly in the severer attacks. Œsophageal pain is relieved for two reasons. In the first place, this symptom may be secondary to gastric irritability and when the latter is removed by food the œsophageal pain disappears. Secondly, the act of swallowing temporarily clears the œsophagus of material likely to irritate either the mucous membrane or muscular coat, but the symptoms are very likely to recur as will be described later. In addition to this inhibitory influence in putting an end to the muscular over-action which is causing the symptoms, it is self-evident that another factor must be concerned—namely, the removal of the cause of the disturbance, otherwise it is doubtful whether inhibition would achieve its object so frequently.

The actual exciting cause of the muscular over-action and that which determines its appearance at a stated regular time, is the condition of the gastric contents as regards their irritant nature. This increases as digestion proceeds owing to the increasing acidity and to the fact that the least irritating and most digestible portions leave the stomach first. The effects of each of these two factors are neutralised by the eating of food. The meal dilutes the residual contents of the stomach and if it be rich in protein, combines with the free HCl. An alkali without materially increasing the bulk of the gastric contents frequently relieves the pain by neutralising the free HCl; but food not uncommonly relieves the pain when there is a normal acidity or no free HCl in the stomach at all. Of 130 cases of pain in the sterno-umbilical region, 48 showed hyperacidity, 29 normal acidity, and 53 diminished acidity or achlorhydria. Of these cases 42 were *relieved by food* as shown in Table VI.

TABLE VI.—*Relief of Pain by Food.*

Acidity.	Occurrence of pain.				Cases.
	At once or quite soon.	½–1 hr.	1 hr. up.	Irreg.	
Hyperacidity ..	—	1	17	—	=18
Normal acidity ..	—	4	9	—	=13
Diminished acidity or achlorhydria..	—	3	8	—	=11
Total	—	8	34	—	42

In all these cases of relief by food the pain occurred usually later than one hour after food. Forty-three were *unrelieved* as in Table VII.

TABLE VII.—*Pain Unrelieved by Food.*

Acidity.	Occurrence of pain.				Cases.
	At once or quite soon.	½–1 hr.	1 hr. up.	Irreg.	
Hyperacidity ..	4	2	2	5	=13
Normal acidity ..	2	1	1	4	= 8
Diminished acidity or achlorhydria..	6	7	1	8	=22
Total	12	10	4	17	43

In these cases in which the pain was not relieved it occurred especially in the early stages of digestion or irregularly.

In the remaining 45 cases the *relief was temporary*, partial, occasional, or by vomiting. Of these, 17 showed hyperacidity, 8 normal acidity, and 20 diminished acidity. It is quite clear, therefore that food may relieve the pain whether the gastric contents are acid or neutral in reaction; that when the pain occurs late it is in either case more likely to be relieved than when it appears early or irregularly and that even when hyperacidity is present the pain may not be relieved at all. In the case of the relief of late pain the contents are neutralised and diluted if they are acid; but diluted only if they are neutral and in both cases the bulk of the meal brings into play the inhibitory mechanism. The latter is the only factor concerned in the relief of pain occurring in the earlier stages of digestion, when the symptoms depend more upon the condition of the nervous system than upon that of the nature of the gastric contents, and the relief in this case is therefore more doubtful.

ERUCTATION.

Eructation is due to excessive pressure in the stomach in relation to the tone of the cardiac sphincter at the time. Both fluid and gas may be brought up, but it is particularly gas in the stomach upon which the patient concentrates his mind and endeavours to eructate in order to relieve his symptoms. He thus acquires the habit, which at the same time involves the swallowing of air. Nevertheless, a good deal may be learned as to the course of events in the stomach from a study of eructation because in addition to its occurrence as a symptom and the habit arising from it, the condition gives rise to changes in the œsophagus which cause secondary œsophageal symptoms. It is necessary to speak separately of the eructation of fluid and gas, although it is not easy to do so because they so often occur together. This analysis is as accurate as can be obtained, for it must be remembered that in dealing with all these symptoms a generous allowance must be made for errors, which are inseparable from the study of symptoms, particularly such irregular ones as those now under consideration.

Eructation of Fluid.—The patient complains of the fluid tasting like acid or vinegar, or as being bitter tasteless, or of some other taste imparted by the stomach contents. There is no difficulty in selecting a definite group in which acid eructations occur, but the second group presents difficulties, although the taste may be uniformly bitter or otherwise, for the patient may be doubtful whether it has any acid taste or not, or occasionally it may be acid but usually not.

Of 677 cases fluid was eructated by 307, giving a percentage of 45·3. The fluid was definitely acid in 164 cases, and in 143 it belonged to the second group.

Of the 164 cases with *acid eructations* 101 were associated with isolated areas of pain and 63 with combined areas. The total number of cases with isolated pain examined was 461, so that of these 101 eructated acid-tasting fluid. A combination of the areas of isolated pain which represent the two portions of the stomach and the œsophagus respectively give the following percentages:—

Total cardiac cases	143	with acid eructations in	23 (16%)
,, pyloric ,, ...	201		57 (28·3%)
,, œsophageal cases ..	117		21 (17·8%)
	461		101

So that acid eructations are more common in pyloric than in cardiac or œsophageal cases, and in the two latter they are more or less equal in number.

Of the 143 cases with *eructations of bitter, tasteless or doubtfully acid fluid* 86 occurred with isolated pain and 57 with combined pains. Combining the areas of isolated pain which represent the two portions of the stomach and the œsophagus respectively, the following percentages are obtained:—

Total cardiac cases ..	143	with bitter, &c., eructations in	33 (23%)
,, pyloric ,, ..	201		29 (14·4%)
,, œsophageal cases ..	117		24 (20·5%)
	461		86

It may be very generally stated that this type of

eructation is a little more characteristic of cardiac and œsophageal pain than of pyloric pain, whereas acid eructations are more characteristic of pyloric pain. I shall show later that the so-called hyperchlorhydria is really a condition of irritability of the pyloric sphincter in which its function, as regulator of the acidity of the gastric contents in the later stages of digestion, is interfered with. Hyperacidity of the gastric contents is the usual but not the necessary result, since the condition may occur when the gastric juice is lessened in amount, in which case the acidity may be diminished, and the eructated fluid doubtful. On the other hand, in affections of the body and œsophagus the gastric contents are neutralised normally, and the eructated fluid is neutral and frequently bitter from the presence of peptones or bile; moreover, hypochlorhydria is commoner in affections of the body. If eructation, however, appears early before neutralisation has occurred then the fluid may taste sour.

Now it is quite clear that a primary irritation of the œsophagus will not give rise to the eructation of acid material, so that such patients must either be cases secondary to irritability of the stomach or the eructation must have been voluntarily produced in the effort to bring up gas and so relieve the symptoms. This question can only be settled by a careful consideration of the case at the time of examination. On the other hand, the eructation of tasteless and neutral fluids may occasionally be entirely due to the œsophagus, the fluid consisting of saliva and mucus which has been swallowed and retained in the œsophagus owing to hypertension of the cardiac sphincter, as Hurst [1] describes.

Fluid Eructated.—The material is usually a thin, watery fluid, and food may be present if the eructation occurs early or even late, if the stomach empties slowly, and there is diminished acidity. The acidity is due to HCl, as the formation of organic acids by carbohydrate fermentation is practically unknown in functional disturbance of the stomach. The amount of fluid eructated naturally varies considerably, and is at its maximum in the condition of hypersecretion of gastric juice, particularly if the stomach empties slowly. In such a condition large amounts may be eructated and spat out in mouthfuls at irregular times and in a nervous subject vomiting may result. Sometimes the patient feels a preliminary sudden tense feeling or even a pain as the stomach contracts, which may awaken him in the night; but large amounts may be present in the stomach without any eructation if the stomach is not irritable. The patient may also eructate fluid soon after a meal, and in such cases, when an opaque meal is given, the food may be seen by the X rays to fall to the lower pole of the stomach through the fluid. The reaction of the fluid depends upon the neutralisation process, if the pylorus is acting normally the reaction is neutral, but if pyloric hypertension is present it is acid. Another possible factor is the passage of neutral chloride under certain circumstances through the gastric mucous membrane. When large amounts of fluid are eructated the condition is spoken of as pyrosis or, particularly if the fluid is neutral, as waterbrash. It has been considered that this waterbrash is largely composed of saliva which has been swallowed in considerable quantity. It can, however, be shown that the fluid of waterbrash is chiefly derived from the stomach by estimating the amount of total chloride it contains, for human saliva only contains between 0·05 and 1 per cent. chloride. In one case eructation occurred two hours after food and in the night, beginning with a sensation as of "something turning over in the stomach." The eructated fluid contained 0·116 per cent. total chloride. From the lower end of the œsophagus were extracted 2 or 3 c.c. of mucus; and at the same time from the stomach was extracted a fluid containing 0·23 per cent. total chloride. In another case the eructated fluid contained 0·158 per cent. total chloride, and the contents extracted from the fasting stomach 0·23 per cent. total chloride. The smaller figures in the eructated fluid are due to dilution during its passage from the stomach. The eructation constituting waterbrash is not essentially different from any other eructation; it is merely a variety in which the sufferer is the subject of hypersecretion.

Eructation of gas, which is practically always air swallowed with the food or with the saliva, or voluntarily, is such a constant symptom that it would seem of little value in diagnosis, but its study is of some use. Out of a total of 694 cases 588 eructated gas, and, as might be expected, all positions of pain were almost equally liable to it.

A combination of the areas representing the two portions of the stomach and the œsophagus gives the following:—

Total cardiac cases ..	.. 153	with gas eructation in	135 (88·2 %)
„ pyloric „ ..	.. 210		165 (79·3 %)
„ œsophageal cases	.. 119		100 (84·0 %)
	482		400

This is a different result from that obtained in the case of fluid eructations, in which the percentage is relatively small, for the majority of patients suffering from gastric disturbance of any type apparently eructate gas in some measure. Comparing this symptom with the sensation of fullness, it will be remembered that the latter symptom was also felt by the majority of cardiac and pyloric cases, but only by half the œsophageal patients. The sensation of fullness in the body of the stomach gives rise to the desire to eructate in order to relieve the feeling, and the voluntary act which usually takes in air also is much more likely to expel gas than fluid, since gas occupies the fundus and this is the part compressed. So that the similarity in the frequency of fullness and gas eructation in cardiac and pyloric cases suggests that the latter symptom is of voluntary origin. This hypothesis is supported by the fact that most œsophageal cases eructate gas, whilst only about half of them feel the sensation of fullness. There is no mechanical reason whatever why the other half of the œsophagus cases who do not feel fullness should eructate gas, and yet they do so; the only reason can be that they do so voluntarily in order to relieve the sensations they feel in the œsophagus. If the eructation of gas were due to excessive pressure in the body of the stomach without any voluntary effort we should expect the percentage of gas eructation to be much smaller and to approximate more closely to that of fluid eructation. This habit of voluntary eructation is difficult to resist by most patients and is more easily established in proportion to the neurotic tendencies of the individual. In the neuropathic patient it may be so marked as to constitute the condition "eructatio nervosa," when at the least feeling of discomfort an attack of air swallowing and eructation commences. In the normal subject the constant swallowing of saliva, mucus, and air in the condition of pharyngeal catarrh increases the air space in the stomach and causes the feeling of fullness and the habit of constant eructation may arise.

The symptom of fluid eructation may now and again also develop into a habit, but in this case there is no air swallowing and the X rays shows a simple contraction of the diaphragm forcing the gastric contents into the œsophagus. The patient may come up complaining of vomiting. Food may be brought up in this way, soon after eating, for years after the fashion of ruminators, but it is spat out, and not masticated and re-swallowed with enjoyment; or sour or neutral fluid may be brought up in quantities at varying times after meals.

I have already stated that irregular pain is more particularly seen in connexion with the body of the stomach in gastric irritability, and that it is frequently dependent upon causes which increase the pressure in the stomach quite apart from the regular abnormalities in the muscular movements of that organ. These same causes give rise to regurgitation into the œsophagus, for example, sitting in a cramped position,

stooping to work, lying down. The patient complains that he gets tightness or pain in the chest with or without eructation. Now it is quite clear that regurgitation occurs to different degrees depending upon the pressure applied to the gastric contents and the varying degrees of resistance offered by the cardiac sphincter, so that a complete eructation occurs into the mouth or an incomplete one into the œsophagus only. There can be no doubt that these incomplete regurgitations are very common and are an important cause of œsophageal sensations. The patient often complains of pain or fullness rising up into the chest, where it takes the form of a tight band, or a lump which may shift up or down and feel like a "wandering bubble," and which may be described as breaking in the upper part of the chest or the throat with a bubbling noise. One patient complained of a pain occurring every few minutes in the central sterno-umbilical region; it passed up to the ensiform cartilage, there attained its maximum, and slowly disappeared with a bubbling sound. If free eructation occurred the pain disappeared at once. Another patient with copious fluid eructations said if the material came up there was no pain, but if not he had pain in the region of the ensiform or an aching, burning sensation or as of a lump sticking there. These instances could be multiplied indefinitely. The symptoms produced depend upon the resulting muscular tension set up in the œsophagus and its sensitiveness, which in their turn depend upon the condition of irritability of the nervous system. Regurgitation can often be seen by the X rays in the absence of any symptoms whatever. Eructations of gas are, therefore, of no value in most cases in the diagnosis of the condition of the stomach, except that when excessive they indicate an unstable nervous system. They are, however, of importance in that the retention of gas in the œsophagus causes symptoms more particularly in the upper part of the chest. Eructations of fluid are, on the other hand, of considerable importance as indicating the state of affairs in the stomach, and are much less dependent upon the condition of the nervous system. They give rise to symptoms more particularly in the lower part of the chest. Complete eructations relieve the pain, at all events for a short time, by lessening the pressure in the stomach and so diminishing the contraction tension of the muscular fibres. Poulton described this relief to the pain of gastric ulcer as occurring on lessening the pressure by the passage of a tube.

VOMITING.

Vomiting is the natural means whereby the stomach is relieved of its contents when they are sufficiently irritating. The stimulus acts upon the vagus endings in the mucous membrane so that vomiting is likely to be more common when the irritant focus is in the stomach than when it is in the œsophagus, in which case the vomiting is of a different type. It relieves the symptoms if the stomach is completely emptied, unless there is a great deal of nervous irritability of the stomach.

It is commonly preceded by nausea, but not invariably so. As a symptom of diagnostic importance, nausea is not of much value, because it is found so irregularly in such a multitude of conditions; on the other hand, vomiting is of the greatest importance. Vomiting occurred in 230 of the series of 1009 cases—that is to say, in 22·8 per cent. It is thus a much less frequent symptom than pain and indicates a higher degree of irritation of the stomach. It is induced in several different ways so that to assess its value and significance a careful history of the origin and onset of the vomiting must be taken to put it into its true category, for however it may arise the reflex tends to become more excitable and the vomiting lose its initial character. The vomiting may then become incessant, occurring if a bad attack is present whenever anything, even water, is put into the stomach. Vomiting is commonly induced not only by conditions of the alimentary canal but also by reflexes from other parts of the body, by affections of the central nervous system, and by blood poisons. It is thus a very important symptom, so that its associated conditions and the circumstances which indicate that it is of gastric origin deserve close attention. Of the 230 cases, 158 occurred with isolated areas of pain and 72 with combined areas. The isolated areas are shown in Table VIII.

TABLE VIII.

Region.	Cases.	Out of a total of—
Upper sternal	4	53 (7·5%)
Lower sternal	18	119 (15·1%)
Upper st.-umbilical	55	223 (24·6%)
Middle „	43	152 (28·2%)
Lower „	17	77 (22·0%)
Right 9 c.c.	16	35 (45·7%)
Left 9 c.c.	5	14 (35·7%)
	158	673

On combining the areas which represent the two portions of the stomach and the œsophagus respectively, the following is obtained:—

		With vomiting in
Cardiac cases	223	55 (24·6%)
Pyloric cases	278	81 (29·1%)
Œsophageal cases	172	22 (12·7%)

Vomiting is thus of almost the same frequency in pyloric as in cardiac cases, the difference being very little, whilst it is only half as frequent in œsophageal cases. It seems, therefore, quite clear that cases in which the irritable focus is situated in the body or pyloric end of the stomach are more likely to vomit than when it is situated in the œsophagus. This fact is due to the different causes operative in each case. The chief cause of vomiting is *pain*, or at all events the same degree of irritation which causes severe pain is likely to cause vomiting, for in the 230 cases of vomiting this act occurred when the pain was at its height in 146—that is to say, in 63·4 per cent. Of these 146 cases of vomiting dependent upon pain, 97 occurred with isolated pain areas as in Table IX.

TABLE IX.

Region.	Cases of vomiting due to pain.	Out of a total of—
Upper sternal	0	4 (0)
Lower sternal	5	18 (27·7%)
Upper st.-umbilical	32	55 (58·2%)
Middle „	34	43 (79·0%)
Lower „	14	17 (82·3%)
Right 9 c.c.	10	16 (62·5%)
Left 9 c.c.	2	5 (40·0%)
	97	158

Combining the areas which represent the two portions of the stomach and the œsophagus respectively, the following is obtained:—

		With vomiting due to pain.
Total body cases	55	32 (58·2%)
„ pyloric „	81	60 (74·0%)
Total œsophageal	22	5 (22·7%)

These figures show that pain due to the pyloric region of the stomach is more likely to cause vomiting than pain due to the body and that œsophageal pain is least likely of all to cause vomiting.

The next cause of vomiting is *regurgitation of fluid* from the stomach. There were 27 cases of this type in the series, giving a percentage of 11·7. The fluid either irritates the fauces or enters the larynx and causes coughing and retching. Attempts at voluntary eructation also lead to retching. Vomiting is thus excited and may become established. This condition is seen especially in neurotic subjects and occurs more particularly in œsophageal cases. More than half the vomiting in œsophageal cases is due to this cause, but only a small proportion of cases of vomiting due to irritation of the stomach are so produced.

Twenty-one of the 27 cases occurred in isolated areas and were distributed as in Table X.

TABLE X.

Region.	Cases.	Due to regurgitation.
Upper sternal	4	4 (100%)
Lower sternal	18	10 (55·5%)
Upper st.-umbilical	55	3 (5·4%)
Middle „	43	2 (4·6%)
Lower „	17	0 (0)
Right 9 c.c.	16	1 (6·2%)
Left 9 c.c.	5	1 (20·0%)
	158	21

Combining these areas the following is obtained :—

Cardiac cases	55	3 (5·4%)
Pyloric cases	81	4 (5·0%)
Œsophageal cases	22	14 (63·3%)

Another cause of vomiting is the *voluntary one*, in hich the patient makes himself vomit to relieve his mptoms. He thinks there is "something to come p," eructation does not relieve him, and therefore e makes himself vomit by irritating his fauces; or e has experienced relief by vomiting and develops he habit to relieve his pain. He may find after a hile that he cannot stop vomiting and comes up omplaining of it as the chief symptom.

There were 23 cases of voluntary vomiting in the 30, giving a percentage of 10. The distribution of 3 cases associated with isolated pain areas is as own in Table XI.

TABLE XI.

Region.	Cases.	With voluntary vomiting.
Upper sternal	4	0 (0)
Lower sternal	18	1 (5·5%)
Upper st.-umbilical	55	7 (12·7%)
Middle „	43	4 (9·3%)
Lower „	17	2 (11·7%)
Left 9 c.c.	5	0 (0)
Right 9 c.c.	16	2 (12·5%)
	158	16

Combining these areas we obtain the following :—

Body	55	7 (12·7%)
Pyloric	81	8 (9·8%)
Œsophageal	22	1 (4·5%)

Only a small proportion of people with œsophageal mptoms make themselves vomit, and of these the fection is in the lower œsophagus. More people ith pain referable to the stomach vomit voluntarily, pecially those with pain in the cardiac portion. omiting is thus chiefly produced to relieve pain in e stomach itself.

These three factors—pain, regurgitation, and luntary vomiting—account for the great majority vomiting in gastric disturbance, for 134 out of 158 ses fall into these groups—i.e., 84·8 per cent. at is to say :—

42 out of 55 body cases	76·3 per cent.
72 „ 81 pyloric cases	88·8 „
20 „ 22 œsophageal cases	90·9 „

It is thus evident that the majority of cardiac d pyloric cases vomit on account of pain or volunily to produce its relief, whilst most œsophageal ses vomit as the result of faucial irritation from gurgitation; and those who vomit on account of in are affections of the lower part of the œsophagus the most part.

The remaining 34 cases—that is, 14·7 per cent. of e total—complained of vomiting at quite irregular aes, unconnected with any of the causes discussed ove. They were all cases in which the nervous ment was especially marked. The symptoms were ophageal in two cases only, and the remainder gastric origin. Sixteen of these patients were able to assign any cause for the vomiting, which curred at any time. Ten were liable to vomit ilst eating, or quite soon afterwards; either the act of masticating and swallowing caused the vomiting, or the stomach was at the time so irritable that contact of the food with the gastric mucous membrane acted as an emetic. The characteristic feature of this type is its variability according to circumstances, which shows that it is a neurotic manifestation. In five cases the vomiting was preceded by a sudden attack of nausea, and in three quite clearly followed on any emotional disturbance.

WASTING.

The remaining symptoms of gastric disturbance do not assist much in explaining the course of events in dyspepsia, and it is not my intention to discuss generally all the manifestations of this disorder. The state of the tongue and other symptoms upon which such stress used to be laid are of little value. Allusion may, however, be made to *wasting*, because it is such an important symptom in cancer and pyloric obstruction and also in certain remote diseases with gastric symptoms. Functional disturbance of the stomach, including uncomplicated ulcer, does not cause wasting, but this symptom may be associated with it in three conditions. The first is severe vomiting; the second is the voluntary reduction of the food to relieve the symptoms or because the patient is afraid to eat; and the third is loss of appetite with nausea. All these are mostly indications of a neurotic individual. The patient cuts off first one foodstuff and then another which he imagines disagrees with him, till he is living on a very reduced diet and becomes wasted, for he usually cuts off the wrong articles. The wasting impairs his nervous system and the symptoms become aggravated. Two other conditions may be referred to briefly, and these are the *condition of the appetite* and the *sex* of the individual; the former because it is commonly supposed to be an index of the condition of the gastric secretion and loss of appetite is of such regular occurrence as an early symptoms of carcinoma ventriculi; the latter, because of the great instability of the nervous system in the female sex.

APPETITE.

Out of a series of 233 cases, 135 had a good, 37 a fair, and 61 a bad, appetite. Of these cases 146 suffered from pain affecting isolated areas.

Combining these areas together we obtain the results shown in Table XII.

TABLE XII.

Region.	Good ap.	Fair ap.	Bad ap.	—	
Cardiac cases	31	11	12	=54	146
Pyloric cases	42	8	9	=59	
Œsophageal cases	18	5	10	=33	

The percentages derived from the figures given in Table XII. are as follows :—

		Per cent.
Cardiac cases	Good appetite in 31 of 54	57·4
	Fair or bad appetite in 23 of 54	42·6
Pyloric cases	Good appetite in 42 of 59	71·1
	Fair or bad appetite in 17 of 59	28·9
Œsophageal cases	Good appetite in 18 of 33	54·5
	Fair or bad appetite in 15 of 33	45·4

The appetite was good in most of the pyloric cases. These include the most robust individuals, usually with hyperacidity of the gastric juice and sometimes with hypersecretion, and contain the smallest number of neurotics. A smaller number of cases affecting the body or œsophagus had a good appetite, for, practically speaking, about half had a good and half had a fair or bad appetite. These include the largest number of neurotics. The œsophageal cases with a good appetite were especially those in which the lower œsophagus was affected, most of whom were likely to be secondary to the pyloric region of the stomach.

SEX.

Out of a total of 830 cases, 476 were males and 354 females. Table XIII. is an analysis of the isolated areas of pain :—

TABLE XIII.

Region.	Males. Occurrence of pain. At once or quite soon.	½–1 hr.	1 hr. up.	Irreg.	Cases.	Females. Occurrence of pain. At once or quite soon.	½–1 hr.	1 hr. up.	Irreg.	Cases.
Upper sternum ..	7	2	2	16	=27	10	1	1	13	=25
Lower sternum ..	8	9	20	11	=48	7	6	12	17	=42
Upper st.-umb. ..	11	13	41	13	=78	24	16	20	23	=83
Middle ,, ..	5	3	60	7	=75	7	9	22	15	=53
Lower ,, ..	—	3	31	3	=37	1	1	14	1	=17
Right 9 c.c. ..	—	3	22	—	=25	—	1	6	—	= 7
Left 9 c.c. ..	—	—	13	1	=14	1	—	6	2	= 9
Total	31	33	189	51	304	50	34	81	71	236

Combining the areas given in Table XIII., we obtain the following :—

Males.

Cardiac cases ..	78	out of a total of	304 ..	.. 25·6%
Pyloric ,, ..	151	,,	304 ..	.. 49·6%
Œsophageal cases	75	,,	304 ..	.. 24·3%

Females.

Cardiac cases ..	83	out of a total of	236 ..	.. 35·1%
Pyloric ,, ..	86	,,	236 ..	.. 36·4%
Œsophageal cases	67	,,	236 ..	.. 28·3%

In males the pyloric region is affected twice as often as the body of the stomach. In females the pyloric region or the body are affected to about an equal degree. The œsophagus gives rise to symptoms about equally in both sexes. This result was to be expected, since females have the more unstable nervous system, and therefore that part of the stomach most affected by nervous disturbance should be relatively more affected in them than in males. Still, females suffer as much from the pyloric end as the body, and so it is hardly justifiable to say that the relatively high proportion of the affections of the body in this sex is due to the fact that their stomachs are more of the so-called hypotonic type than are those of males. Neither is it justifiable to say that the form of dyspepsia from which the patient suffers is due to the shape of the stomach. Mills described four normal types of stomach according to the bodily habitus of the individuals possessing them. (1) The hypersthenic type, comprising about 5 per cent. in which the stomach is high in position, has the fastest motility, and most marked tonus of any type. (2) The sthenic type, comprising about 48 per cent., in which the stomach is fairly high, with good tonus and fairly rapid motility. (3) The hyposthenic type, comprising about 35 per cent., in which the stomach is fairly low, with rather poor tonus and motility. (4) The asthenic type, comprising about 12 per cent., in which the stomach is often largely pelvic, has poor tonus and slow motility. It is quite certain that normal individuals vary about a certain average, not only as regards the position and shape of the stomach, but also as regards each of its functions. The type of stomach affected must produce some modification in the resulting processes produced by any disturbance, but this effect must not be overexaggerated, for all people, whatever the sex or shape of the stomach, are liable to the same affections, and any difference in the liability of any individual to any particular affection is due to the different make-up of the nervous system and the habits of the patient. The nervous tendency of the female is illustrated by comparing the two sexes as regards time of onset of symptoms. The female shows in every position of the pain a much greater tendency than the male to feel the pain quite early in the digestive process and also irregularly. For example in the upper sterno-umbilical position the 78 males show regular pain from ½ hour upwards in 54 cases but early and irregular pain in 24 only. The 83 females, on the other hand, show regular pain from ½ hour upwards in only 36 cases, but early and irregular pain in 47 cases. And so all the way through. The greater number of cases of late pain in each position in the male appears to indicate that more of the cardiac and œsophageal cases in this sex are secondary to the pylorus and less of primary condition than in the female.

It is quite common for the hyposthenic and asthenic types of stomach to be referred to as "dropped." An organ can only be said to be dropped if it has originally occupied a higher position than at present, but all these four types are normal to the individuals possessing them and are developmental. The only form of gastroptosis which exists is that associated with varying degrees of visceroptosis owing to relaxation of the abdominal wall, and if any disorder is present, whether it is purely nervous or one which delays the emptying of the stomach, such stomachs must suffer more severely than those unassociated with this condition.

ORGANIC LESIONS OF THE STOMACH.

The only two lesions which need be mentioned here are gastritis and uncomplicated ulcer. Gastritis is no doubt, common enough; it is present to some degree in all chronic ulcers. I shall refer to this condition later on, and at the moment merely say that, when it does produce symptoms, they are indistinguishable from those due to irritability of the body of the stomach, except by the type of vomiting and an examination of the stomach contents, and they are rare in comparison with the bulk of gastric cases. Ulcer, on the other hand, is a very common affection and of great importance from our present point of view, because we know its position and therefore where the irritable focus causing the symptoms is situated. Whichever side of the pylorus the ulcer is situate, its effect in causing irritation of the sphincter is the same, so that duodenal ulcer must be considered with gastric ulcer. A comparison of the pain of gastric and duodenal ulcer with that of the cases already examined shows that it is essentially the same in all particulars and due to the same causes. There are two series of cases; the first is one of 85 cases of duodenal ulcer, and the second of 59 cases of gastric ulcer. All were operated upon and shown to be free from complications. Of the 85 cases of *duodenal ulcer*, 70 showed isolated pain and 15 various combinations. The isolated areas of pain were as follows :—

Upper sterno-umbilical region ..	..	in	9 cases.
Middle ,, ,, ..	..	,,	22 ,,
Lower ,, ,, ..	..	,,	16 ,,
Right 9 costal cartilage region ..	..	,,	17 ,,
Right and left 9 c.c. region	..	,,	6 ,,

Combining these areas together so as to represent the different regions of the stomach, the following result is obtained :—

Cardiac pain	..	12·2	per cent. of cases.
Pyloric pain	..	87·1	,, ,,

It is, therefore, quite clear that duodenal ulcer causes pyloric pain in the majority of cases, but in a certain number the pain is cardiac. In exceptional cases a chronic duodenal ulcer causes no pain whatever in any position, the only effects being a sense of fullness and regurgitation of the gastric contents. Now this result agrees with our conception of pyloric irritability already formed—namely, that pyloric pain is the usual result, but sometimes backward effects without pain occur, the symptoms being attributable to the body and œsophagus only. The

difference from simple functional disorder is that a larger proportion of patients with duodenal ulcer suffer from pyloric pain, having the empty sensation of hunger, and a smaller proportion backward effects only. The explanation is that duodenal ulcer belongs chiefly to the group I have mentioned, in which the pain occurs later than usual and when the stomach is almost empty, hypersecretion is present, and pyloric spasm is more common. Of the 59 cases of *gastric ulcer*, 23 were described by the operating surgeon as being near the pylorus and 36 in the body of the stomach.

The 23 *pyloric cases* gave rise to localised pain in 18 and combined pain in 5 cases. In 18 cases the pain was distributed as follows:—

Upper sterno-umbilical area	in 2 cases.
Middle " "	" 6 "
Lower " "	" 8 "
Right 9 costal cartilage	" 1 case.
Left 9 c.c.	" 1 "

The regions of the stomach represented by these areas are as follows:—

Cardiac pain	in 11·1 per cent. of cases.
Pyloric pain	" 88·8 "

Pyloric ulcer, therefore, usually causes pain in the pyloric area, but sometimes, as in duodenal ulcer, a backward effect on the body of the stomach is the only symptom. The 36 ulcers in the *body of the stomach* caused pain in isolated areas in 20 and combined areas in 16. The pain in the 20 body ulcers was distributed as follows:—

Upper sterno-umbilical area	in 12 cases.
Middle " "	" 5 "
Lower " "	" 2 "
Left 9 c.c.	" 1 case.

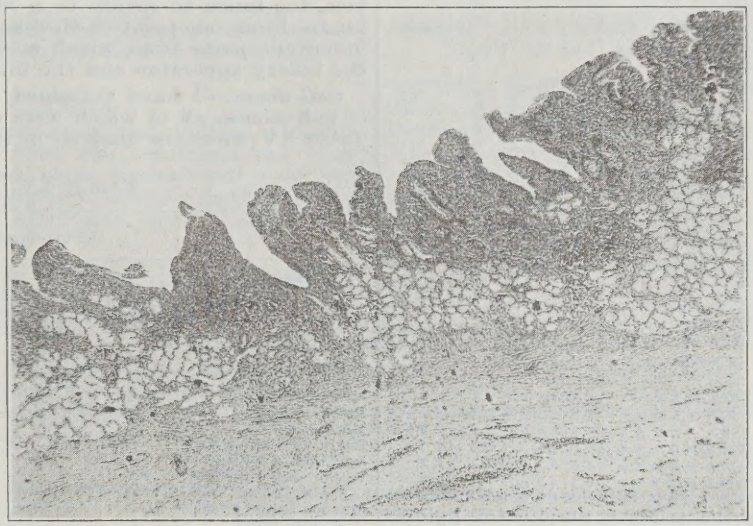
The percentages affecting the different regions of the stomach are as follows:—

Cardiac pain	in 60 per cent. of cases.
Pyloric pain	" 40 "

The majority of ulcers of the body of the stomach cause definite cardiac pain, but in a smaller number of cases pyloric pain. This fact has been commented upon before by various observers and there can be no doubt that an ulcer of the small curvature situated in the pyloric vestibule, although some distance from the sphincter, may give rise to irritability of this structure through the mysenteric plexus.

The number of these cases is small, but they are enough for our purpose. The patients with multiple areas of pain in all these cases showed similar combinations to those already described. These results appear to indicate that the pain is not produced by irritation by the gastric contents of any afferent nerve-fibres in the base of the ulcer, because if this were the case the position of the referred pain should always accurately indicate the position of the ulcer.

FIG. 2.



Scar of duodenal ulcer. The patient complained of gnawing pain one hour after food, relieved by eating.

The alternative explanation is that the pain indicates the particular segment of the stomach which the ulcer is chiefly irritating. A duodenal ulcer or a pyloric ulcer acts as a focus of irritation to the pylorus with secondary cardiac symptoms. The pain is nearly always of the pyloric type, but occasionally the body of the stomach is the source of pain. An ulcer in the body of the stomach acts as a focus of irritation to the cardiac portion of the stomach, but in a smaller proportion of cases irritates the pylorus owing to its position, so that the pain, though usually of the cardiac type, is often of the pyloric type. Not only is the pain of an ulcer of precisely the same nature as that of simple functional disturbance, but it obeys all the laws applying to it. There is no distinction between them and it is quite impossible to separate them clinically. The pain comes on during digestion and ceases when food is eaten or when the stomach is empty or after vomiting. The pyloric and duodenal cases show the pyloric type of pain—that is to say, pain occurring in the later stages of digestion—and the cardiac cases the cardiac type of pain which occurs earlier and often irregularly.

These ulcers show combinations of the pain areas of precisely the same nature as the functional cases, and the posterior pain corresponds to the pain in front. All the remaining characters described in relation to gastric pain—for example, the increasing irritability of the stomach with the lapse of time, the intervals of freedom from alternating with attacks of pain, the ready relief of pain by dieting, the dependence of pain upon the condition of the nervous system, and of the health of the patient, the relief of pain by alkalis and food are in agreement with the hypothesis that the pain of gastric ulcer depends entirely upon the fact that the ulcer acts as a focus of irritation to the neuro-muscular mechanism of the stomach. A further point of importance is that the ulcer is still unhealed in the intervals of freedom from pain and the attacks of pain are influenced by exciting causes similar to those existing in functional disturbance. It is quite impossible to foretell in any given case what is the condition of the ulcer. It may be healing, or even healed, and yet the same kind of pain may be present. It is not uncommon to find the ulcer advanced in healing in a fatal case of hæmatemesis, and sometimes ulcers excised by operation are shown by microscopic examination to be healed (Fig. 2). It is also a matter of common knowledge that the abdomen is frequently demonstrated to be free from any organic disease whatever at operations undertaken for the relief of gastric pain mistaken for that of ulcer. The following 33 cases of gastric pain, all of which were thought to be the subjects of gastric or duodenal ulcer, were explored quite thoroughly and no lesion whatever was demonstrable in the

duodenum, stomach, or the rest of the abdomen. They are as shown in Table XIV.

TABLE XIV.

Region.	Occurrence of pain.				Cases.
	At once or quite soon.	½–1 hr.	1 hr. up.	Irreg.	
Upper st.-umbilical	2	1	2	2	=7
Middle st.-umb. ..	1	2	2	3	=8
Lower st.-umb. ..	—	—	1	2	=3
Upper sternum ..	—	—	—	1	=1
Lower sternum ..	—	—	—	1	=1
Right 9 c.c.	—	—	4	—	=4
Right and left 9 c.c.	—	—	1	—	=1
Left costal m. whole	—	1	1	—	=2
Upper st.-umb. and right 9 c.c... ..	—	—	1	—	=1
Upper st.-umb. R. and L. 9 c.c. ..	—	—	—	1	=1
Upper st.-umb. and left 9 c.c.	—	—	1	—	=1
Upper st.-umb. and whole sternum ..	—	—	1	—	=1
Middle and lower st.-umb.	—	—	1	—	=1
Upper middle and lower st.-umb. ..	—	—	1	—	=1
Total	3	4	16	10	33

This series is not an average sample of the dyspeptic population, because the relative number of pyloric cases is too high, and of the œsophageal cases too low. Considering the isolated areas of pain only, the percentages are as follows:—

Œsophageal pain	8 per cent.
Cardiac pain	28 „
Pyloric „	64 „

Of the total dyspeptic cases the percentages are:—

Œsophageal pain	25·3 per cent.
Cardiac pain	33·4 „
Pyloric „	39·7 „

They, however, agree quite well with a series of ulcer cases in which pyloric pain is relatively high. The ulcer cases quoted above show the following percentages:—

Œsophageal pain	Nil.
Cardiac pain	27·7 per cent.
Pyloric „	71·9 „

The right type of case has, therefore, been selected for operation, except that no case showing isolated œsophageal symptoms should be subjected to operation without some other very definite evidence of ulcer. The treatment for an ulcer of the stomach is precisely the same as that for acute or chronic irritation of the stomach—that is to say, the adoption of the appropriate means to remove the gastric irritability produced by the ulcer—namely, rest for the stomach, reduction of its work, and reduction of its acidity. Finally, the curves of acidity obtained from cases of ulcer demonstrate what parts of the stomach are irritated. My own statistics show that some 78·9 per cent. of the curves obtained from cases of duodenal ulcer are of the pyloric type, and that about 90 per cent. of the curves of acidity of pyloric ulcers show similar curves. On the other hand, about 77·7 per cent. of the curves obtained from ulcers of the body of the stomach are normal in type and indicate that the pylorus is acting normally. Ryle [2] quotes a series of cases of duodenal ulcer showing hyperchlorhydria in 68 per cent., and of gastric ulcer showing normal curves in 75 per cent. of cases. Hunter [3] gives 88 per cent. hyperchlorhydria in duodenal ulcer and 67 per cent. in pyloric ulcer, and 35 per cent. in cardiac ulcer.

REFLEX EFFECTS ON THE STOMACH.

Irritability of the stomach may arise as a reflex effect from some other organ, more especially a part of the alimentary system. Craven Moore [4] calls this reflex dyspepsia. Our certain knowledge of this subject is fragmentary and it is difficult to decide what reliance should be placed upon the X ray appearances described. A great deal has been written from different points of view on the question as to how the stomach is affected by these reflexes; in fact, too much to review in a clinical study of this kind. From our point of view as clinicians the most important parts from which such reflexes arise are the biliary apparatus and the intestine.

Gall-stones.—I have examined a series of 56 cases of gall-stones, all of which were operated upon, and Table XV. gives the analysis of their pain.

TABLE XV.

Region.	Occurrence of pain.				Cases.
	At once or quite soon.	½–1 hr.	1 hr. up.	Irreg.	
Upper st.-umbilical	2	1	3	2	= 8
Middle st.-umb. ..	—	—	2	—	= 2
Lower st.-umb. ..	—	—	—	1	= 1
Upper sternum ..	1	—	—	2	= 3
Lower sternum ..	2	—	3	3	= 8
Right 9 c.c. ..	—	—	3	1	= 4
Right and left 9 c.c.	—	—	—	1	= 1
Left costal margin .	—	—	—	1	= 1
Upper and middle st.-umbilical ..	1	—	—	1	= 2
Middle and lower st.-umbilical ..	—	—	—	1	= 1
Sense of fullness and gaseous eructations	—	—	—	—	=25
Total	—	—	—	—	56

Almost half the cases complained of a simple feeling of fullness and eructation of gas, symptoms attributable to the body of the stomach, since only five of the patients had acid eructations.

Combining the localised pain areas the following percentages are obtained:—

Œsophageal pain	40·7 per cent.
Cardiac pain	29·6 „
Pyloric „	29·6 „

There is here an excess of cases affecting the body of the stomach and the œsophagus, which is very much greater if the cases of simple fullness are combined with them.

This, I believe, is in accordance with the general medical notion regarding the gastric symptoms associated with gall-stones. Many series of cases with examinations of the gastric acidity in gall-bladder conditions have been published. For example, a series published by Bonar [5] shows 23 per cent. of cases of hyperchlorhydria, and 78 per cent. of cases of either achlorhydria or normal curves. Another series quoted by Ryle [2] gives 21 per cent. hyperchlorhydria and 79 per cent. normal curves or hypochlorhydria. All these are in agreement with the view that in disease of the gall-bladder the body of the stomach is the part particularly affected, and in a smaller number the pylorus. The time of onset of the symptoms is the same as that in any average series of cases; so that in this reflex dyspepsia the type of symptoms entirely depends upon which part of the stomach is irritated. It cannot be expected that one part should always be exclusively affected, but that the incidence should fall more sharply on one part than another.

Intestine.—It is much more difficult to come to a definite conclusion as to the effects upon the stomach of reflex irritation from the intestine, and I have no conclusive series of cases to present at the moment. As regards appendicitis, I will merely say that I thoroughly agree with those observers, and Walton [6] in particular, who deny the existence of chronic appendicitis except as the end-result of an acute attack. In a series of 64 cases of appendectomy for gastric

ymptoms in whom the removal of the appendix roduced not the slightest effect—

Œsophageal pain occurred	..	in 15·5 per cent. of cases.
Cardiac pain occurred ..	..	„ 31·1 „
Pyloric „ „ ..	..	„ 53·3 „

This series is not unlike that in which an operation vas undertaken for supposed ulcer of the stomach.

SUMMARY.

1. From a consideration of the position, time of nset, and relief of pain, the conclusion has been eached that there are three fundamental symptom roups constituting dyspepsia, the pyloric, the cardiac, nd the œsophageal syndromes, each of which has everal different types.

2. There is clinical evidence that the pyloric isorder produces backward effects upon the body nd œsophagus, and the cardiac disorder upon the esophagus.

3. If the patient has neuropathic tendencies the ymptoms are modified in certain ways indicated. he body and œsophagus are more likely to e disturbed in such patients than the pyloric egion.

4. The chief clinical phenomena of these types f disorder are as follows:—

Pyloric Syndrome.—Pain appearing in the pyloric rea during the later stages of digestion. It is ccompanied by secondary cardiac symptoms, either n empty hungry feeling, or a sensation of fullness, r of pain. Vomiting occurs with pain in a certain umber of cases. Pyloric pain may be absent and econdary cardiac symptoms may alone be present. n all the types of cases acid eructations and secondary esophageal symptoms commonly occur. The symp-oms in all cases are relieved by food.

Cardiac Syndrome.—Pain, or fullness only, appearing n the cardiac area during the early stages of digestion, r moderately late, or irregularly. Vomiting occurs vith pain in a certain number of cases. Secondary sophageal symptoms are common, and the fluid ructated is more likely to be bitter or neutral than cid. The symptoms may, or may not, be relieved y food.

Œsophageal Syndrome.—This is either primary r secondary and consist of pain, or one of the minor ensations, in the œsophageal area. The upper and ower parts of the œsophagus differ, in that the ymptoms affecting the latter show, to a considerable xtent, similar time relations to food as the body of he stomach; whereas, in the case of the former he symptoms characteristically appear quite early r irregularly. The symptoms of the lower part may r may not be relieved by food, but the relief fforded to those of the upper part is usually only emporary or partial. Vomiting may occur from egurgitation of fluid, which is of the same nature s that of the cardiac syndrome.

5. Disorders of function as the result of local isease, not structurally altering the stomach, are of the ame nature as those of the idiopathic malady affecting he particular part of the stomach concerned.

6. Disorders of function primarily due to reflex ritability of the stomach are also the same as those f idiopathic origin, and they chiefly affect one or ther part of the stomach, but not exclusively so.

OVARIAN HÆMORRHAGE SIMULATING ACUTE APPENDICITIS.

A SERIES OF SEVEN CASES.

BY R. K. WILSON, M.B. CAMB., F.R.C.S. EDIN.,
SURGEON TO OUT-PATIENTS, SOUTHEND VICTORIA HOSPITAL.

OVARIAN hæmorrhage from a ruptured Graafian follicle or corpus luteum is one of the many conditions which may be mistaken for acute appendicitis.

Occasionally reported in the early part of last century, it was then included in a group labelled apoplexy of the ovary. H. W. Wilson,[1] in 1905, seems to have been the first to note its diagnostic confusion with acute appendicitis. Novak,[2] of Johns Hopkins Hospital, who reviewed the literature up to 1917, was able to collect 40 recorded cases, and Brakeley and Farr [3] have published a summary of 14 which were treated at the New York Hospital between 1914 and 1925, all with a pre-operative diagnosis of acute appendicitis. A number of other observers have reported single cases in which, before operation, the condition was thought to be ruptured ectopic gestation.

Of the following series of seven cases, all but one of which came under my observation, six were admitted to the surgical wards of the London Hospital, and one to the Southend Victoria Hospital. The patients were all women between the ages of 19 and 25.

The Cases Described.

CASE 1.—A shoe operative, aged 19, and unmarried, was admitted to the London Hospital on March 21st, 1924. For a week she had had dull pain in the right side of the abdomen, but this had not prevented her from going to work until two days before admission, when it had become much more severe. She complained of nausea but had not vomited. Her bowels had been open daily, though not as freely as usual. She had had no disturbances of micturition and her periods were regular, the last finishing eight days previously. On *examination:* temperature 98·2° F., pulse-rate 96, respiration-rate 24. Tongue moist and furred. Cutaneous hyperæsthesia over the right iliac fossa and over right ligament of Poupart. Tenderness and slight resistance to pressure in the right iliac fossa, but no rigidity of the abdominal muscles. Per rectum, some fullness in the pouch of Douglas, with slight tenderness. No abnormal constituents in urine. At *operation* the appendix was freely movable and normal in appearance. The left ovary was also normal, but in the right ovary there was a swelling, about the size of a large walnut, which had ruptured into the peritoneal cavity. As the ovary was being delivered through the abdominal wound, a round object, the size of a walnut and looking like a mass of blood-clot, contained in a thin membrane, slipped out of the ruptured cysts followed by dark altered blood and fresh arterial hæmorrhage. The cavity of the cyst was obliterated by a running suture, 2 oz. of blood-clot were swabbed out of the pouch of Douglas, and after the appendix had been removed the abdominal wound was closed without drainage. The patient made an uninterrupted recovery and after discharge had no complaints, menstruation being normal. The *pathological report* was: "Hæmorrhagic corpus luteum; no histological abnormality of appendix."

CASE 2.—An unmarried shop assistant, aged 20, was admitted to the London Hospital on May 4th, 1924. She had had abdominal pain for six days, at first generalised, but for the last 48 hours mostly in the right side. She complained of nausea since the onset of the pain, and had vomited twice during the two days before admission. She had taken an aperient on the night previously, and whilst at stool on the morning of the day of admission had been seized with acute pain in the right iliac fossa, followed by vomiting. Her bowels had been open daily since the onset of pain and she had had no dysuria or frequency. Her menstrual periods had been regular, the last finishing 12 days before. On *examination:* distressed; temperature 98·4° F., pulse-rate 100, and respiration-rate 24. Considerable tenderness in right iliac fossa, lessening to the left of the mid-line. Slight rigidity of abdominal muscles of the right side and cutaneous hyperæsthesia above Poupart's ligament. Per rectum, no swelling or tenderness. Nothing abnormal in urine. *Expectant treatment* was adopted, with the patient in Fowler's position, nothing but water being given by the mouth. After 36 hours

her temperature had not risen, but her pulse-rate, after dropping at first to 88, had risen again to 102, and she was having a good deal of pain. *Operation* was therefore decided upon, and the appendix, which was found freely movable and normal in appearance, was removed. The right ovary was scarred and thickened and showed a hæmorrhagic cyst about the size of a large walnut, apparently on the point of rupture. The left ovary was normal. The cyst was opened, and its contents, blood-clot, removed. The cavity was obliterated and the abdomen closed. The patient made an uninterrupted recovery, and two months after discharge her periods were normal and she had no symptoms. The *pathological report* was: "Blood-clot and fragments of lutein tissue; no histological abnormality of appendix."

CASE 3.—An unmarried domestic servant, aged 20, was admitted to the London Hospital on May 13th, 1924. Two days previously she had been seized with acute colicky pain in the lower abdomen. She had had considerable nausea but had not vomited. Her bowels had been open twice since the onset of the pain; she had had no frequency or pain on micturition and denied any vaginal discharge. Her periods had been regular, the last finishing 21 days before. On *examination:* temperature 99° F., pulse-rate 108, and respiration-rate 26. Tongue furred. Abdomen slightly distended and tender to palpation over the whole hypogastrium, with rigidity of muscles on right side. Cutaneous hyperæsthesia absent. No sign of vaginal discharge. Per rectum, great tenderness and a soft mass high up on the right side. At *operation* a freely movable, apparently normal appendix was removed. The right ovary, which was low down in the pelvis, contained a ruptured hæmorrhagic cyst about the size of a walnut, and there was some blood-clot in the pouch of Douglas. The cyst was dealt with as in the last two cases, and the clot swabbed out of the pelvis. The patient made a good recovery and six weeks after discharge had no complaints. The *pathological report* was: "(1) Slight acute inflammation of peritoneum of appendix. (2) Blood-clot, red and grey thrombus, and layer of lutein cells from cyst of right ovary."

CASE 4.—The patient was a married woman, aged 25, who had had no children or miscarriages. On admission to the London Hospital on May 14th, 1924, she complained of having had sharp intermittent pains in the right side of the abdomen for four days, with nausea but no vomiting. A few hours previously it had increased in severity. Her bowels had been open daily and she had had no disturbance of micturition. Her periods had been regular and normal, the last finishing 11 days previously. She had had a mild attack of somewhat similar pain lasting for two or three days about five weeks before. On *examination:* temperature 99·6° F., pulse-rate 94, and respiration-rate 26. Tongue moist and furred. Some tenderness in right iliac fossa, but no rigidity and no cutaneous hyperæsthesia. Per rectum, slight but definite tenderness on right side. Nil abnormal in urine. At *operation* the appendix was freely movable and normal in appearance. The right ovary contained a hæmorrhagic cyst the size of a hen's egg, which had apparently just ruptured, with escape of dark altered blood. A mass of blood-clot was squeezed out and the cavity examined. There was no definite lining membrane and no fresh hæmorrhage. The cyst was obliterated with a running catgut suture, preserving the ovary. The left ovary was normal in appearance. The appendix was removed and recovery was uninterrupted. Four weeks after leaving hospital on May 31st she complained of a purulent vaginal discharge and also that her periods had not returned since the operation. She was given appropriate treatment for the discharge and advised to discontinue the use of contraceptive pessaries. A month later the discharge had almost gone and her periods had returned. She has since become pregnant. The *pathological report* was: "(1) Appendix—no histological abnormality. (2) Blood-clot and a minute fragment of lutein tissue."

CASE 5.—A shop assistant, aged 24, unmarried, was admitted to the London Hospital on June 1st, 1924. For three days she had been away from work, complaining of abdominal pains and nausea. On the morning of admission the pain had become more severe and localised to the right side, and she had vomited once. Her bowels had been open daily and she had had no disturbance of micturition. Her last menstrual period had begun on May 13th, and had been perfectly normal. On *examination:* in considerable distress; temperature 99·2° F., pulse-rate 112, and respiration-rate 24. Dirty furred tongue. Tenderness in right iliac fossa on palpation; no rigidity or cutaneous hyperæsthesia. Per rectum, tenderness on both sides of the pelvis; no mass felt. No vaginal discharge; urine free from abnormal constituents. At *operation* the appendix was movable and appeared normal, but the right ovary was the size of a golf ball, much thickened and scarred, and showed an unruptured cyst about half an inch in diameter projecting from the outer pole. This was incised and found to contain clear fluid and some blood-clot. The contents were evacuated and the cavity obliterated. The left ovary was normal, and the wound was closed after removal of the appendix. The patient had a slight rise of temperature on the second day after operation; otherwise she made an uninterrupted recovery and was discharged on the fifteenth day. She was seen again six weeks later, when she was free from symptoms. The *pathological report was:* "(1) Appendix: no histological abnormality. (2) Blood-clot and fragment of lutein tissue."

CASE 6.—The patient was a woman, aged 23, who had been married one year without pregnancy. She was admitted to the Southend Victoria Hospital under my care on Jan. 12th, 1928, complaining of six days' intermittent pain in the right side of the abdomen. It had been sharp and sudden in onset and had subsided gradually with exacerbations at intervals of a few hours—in no instance of greater severity than the first attack. The pain had been followed by nausea and she had vomited once. She also complained of two days' dysuria and frequency of micturition, and of dyspareunia. She had no appetite and was constipated. Her periods had always been regular, the last finishing 11 days before the onset of the pain. On *examination:* temperature 99° F., pulse-rate 88, and respiration-rate 26. Tongue moist and slightly furred. Abdomen tender with slight resistance to pressure in the lower right quadrant. No cutaneous hyperæsthesia. Per vaginam, tender mass above the right vaginal fornix, separate from the uterus, which was freely movable and did not seem to be enlarged. No vaginal discharge, and nothing abnormal in urine. As *expectant treatment* she was put to bed in Fowler's position and allowed nothing but water by the mouth. Some 18 hours later her pulse-rate had risen to 114, though her pain had somewhat subsided. The diagnosis of acute appendicitis was made and I decided to explore her abdomen without delay. At operation the appendix showed no abnormality. The right ovary contained a hæmorrhagic cyst the size of a large walnut, which had recently ruptured into the abdominal cavity; fresh arterial hæmorrhage—probably induced by the manipulation necessary to bring the ovary up to the abdominal wound—appeared at the point of rupture. The left ovary was normal. The right ovary and appendix were removed; about 2 oz. of recent blood-clot was swabbed out of the pelvis and the abdomen closed without drainage. This patient made an uninterrupted recovery and was sent home on the fourteenth day after operation. The *pathological report* was: "(1) Appendix: no histological abnormality. (2) The section shows a fibrous ovary with remains of hæmorrhage into a corpus luteum."

The last case of the series is of interest in that it was the only instance of this condition seen at the London Hospital in the year ending May 31st, 1925, whereas the first four cases all occurred within less than three months. I did not see this patient on admission, but I was present at the operation.

CASE 7.—The patient was an unmarried domestic servant, aged 22, and was admitted on April 6th, 1925. For ten days she had complained of abdominal pain, which had been constant, though not at first severe. Three days before admission its severity had increased, and she vomited five times during the night of April 4th—i.e., 36 to 24 hours before admission—and again once 12 hours previously. Nausea had been constant some time before the vomiting began. Her bowels had been open daily since the onset of the attack; two days before admission she had been given an enema. She had had no disturbance of micturition, and her periods had been regular, the last finishing one week before—i.e., three days after the onset of the abdominal pain. On *examination* she seemed in good health and was not distressed. Temperature, 99° F.; pulse-rate, 90; respiration-rate, 24. Tongue moist with patchy white fur. Localised tenderness in right iliac fossa with slight rigidity of abdominal wall in same situation. Cutaneous hyperæsthesia above and below Poupart's ligament on right side. No mass discoverable by palpation. Per rectum, she appeared very tender; this was discounted as being due to nervousness. Urine not examined. At *operation* the appendix seemed to be normal and was removed. The right ovary contained a cyst the size of a golf ball, which burst on delivery, its contents being apparently blood-clot. The right ovary was removed, the tube being left intact. The left ovary was normal. The patient made an uninterrupted recovery, and the *pathological report* was: "(1) Slight acute appendicitis. (2) Hæmorrhagic lutein cyst of right ovary."

Diagnosis before Operation.

In all these cases the symptoms and physical signs were strongly suggestive of acute appendicitis. In three of them the pain was certainly described as

being right-sided only, and not as being generalised or epigastric at its onset; but its severity, the suddenness of its onset, and the absence of symptoms referred to the urinary system, coupled with the physical signs, pointed strongly to the appendix as the seat of the condition. Two of the patients had no rise of temperature, and this is admittedly unusual in acute appendicitis; but here again the absence of a history of amenorrhœa or even the imminence of the next regular period, as well as the absence in each case of any suggestion of uterine hæmorrhage, rather discounted the suggestion of ectopic pregnancy. In one case, the sixth of the series, the possibility of right salpingitis was suggested, but the balance of evidence was distinctly against it.

The common features of these seven cases were pain of sudden onset, tenderness to pressure in the right iliac fossa, and a raised pulse-rate; these symptoms and signs must inevitably suggest acute appendicitis. In five of them the abdomen was opened and the appendix searched for at once; of the remainder, expectant treatment was tried in Case 2 for 36 hours and in Case 6 for 18 hours. In both of them a rising pulse-rate made it clear that further delay was inadvisable if the diagnosis was correct. It is reasonable to suppose that in Case 2, had a confident diagnosis of the true condition been possible before operation, the hæmorrhage and peritoneal irritation would have subsided with complete rest, as the cyst was found at operation to be unruptured with no free arterial hæmorrhage in its cavity. The pathological process had, in fact, stopped, and resolution was apparently taking place. However, as it has been pointed out, a diagnosis, or at any rate a confident diagnosis, of the true condition cannot be made; such symptoms and signs as these cases presented will always point strongly to that common condition, acute inflammation of the appendix.

Brakeley and Farr [3] consider that operative treatment is not indicated in ovarian hæmorrhage of this type, except in rare instances. They quote two cases in which a diagnosis of the condition was made without operation, and which cleared up completely with rest and medical treatment. (One patient had had her appendix removed previously.) They go on to say, however, that—

> "the differential diagnosis is extremely difficult. We found no pathognomonic sign or symptom of hæmorrhage into a Graafian follicle. In case of doubt, observation for a few hours is justifiable, but as there is grave danger from delay in appendicitis, and very little danger from an exploratory operation, it is wiser to operate if the symptoms do not subside."

Moore [4] is impressed with the fact that in none of the cases reported, so far as he could ascertain, was the correct diagnosis made before operation. He gives a summary of 14 cases, including two of his own; ten were diagnosed as acute appendicitis, and four as ruptured ectopic gestation. Eick's [5] and Odermatt's [6] cases were also diagnosed as acute appendicitis before operation.

Furthermore, though the condition might clear up with rest if caught at once in the early stages, four of those I have described had reached the stage of rupture and intraperitoneal hæmorrhage; and Crousse,[7] Goldberger,[8] and Strauss [9] have each reported cases in which the hæmorrhage approached the degree seen in ruptured ectopic pregnancies of the fulminating type, and the patients were only saved from death by immediate operation. Penny's [10] case proves that hæmorrhage of this type can indeed end fatally; his patient died in nine hours, and at necropsy the abdominal cavity was found to be full of blood from a ruptured Graafian follicle.

Thus it will be seen that the condition under review produces two clinical types of case; the first comprising the milder degrees, giving signs of peritoneal irritation and indistinguishable from acute appendicitis; the second, fulminating, presenting the picture of severe intraperitoneal hæmorrhage. Both call for operative treatment.

Course of the Hæmorrhage.

The pathological process underlying this form of ovarian hæmorrhage seems to be an exaggeration of the normal physiological mechanism of rupture of the Graafian follicle, which occurs some time during each menstrual cycle in a sexually active woman. It is believed that a minute hæmorrhage normally takes place into the cavity of the follicle immediately after discharge of the ovum, and that the tiny clot is absorbed by the cells of the membrana granulosa during the process of development into the lutein cells of the ripening corpus luteum. It is suggested that in the cases under discussion this hæmorrhage for some reason assumes pathological proportions, distending the tunica albuginea of the ovary, thereby producing the pain and physical signs, and finally rupturing the hæmatoma so formed at or about the stigma of the original Graafian follicle. This view is borne out by the uniformity of the pathological findings in the seven cases under review; blood-clot and lutein cells were in every case found in the material removed from the ovary.

Shaw [11] believes that ovulation—i.e., extrusion of the ovum—takes place between the thirteenth and sixteenth days of the menstrual cycle. If the above view of the pathology of these cases is correct, then the onset of the symptoms might be expected to bear some similar constant relation to the first day of the preceding period. Unfortunately, exact notes on this point were not taken in my series of cases. Except in one of them, the symptoms seem to have started somewhere about midway between the periods.

What, then, is the factor which causes the hæmorrhage into the cavity of the follicle to become excessive? Schumann [12] believes that it is generally disease of the ovarian vessels. Primrose [13] reported two cases in which trauma played a part; in one of them a normal Graafian follicle ruptured during a sudden strain while lifting a heavy box, whilst the other was attributed to violent vomiting. Novak [2] quotes von Beust as having found nine cases out of 36 in which trauma was regarded as having started the hæmorrhage. In Crousse's [7] case rupture occurred during a bimanual examination, but possibly the cyst was already hæmorrhagic. H. W. Wilson [1] pointed out that these cases occur essentially in young women whose ovaries are at the height of their functional activity and who are often in a state of relatively high sexual excitement. In my series of cases nothing suggests a common ætiological factor. There is certainly no history of trauma in any of them.

Cases at the London Hospital.

An examination of the records of the London Hospital shows that during the nine years, 1915–23, nine cases of hæmorrhagic lutein cyst of the ovary were admitted to the *surgical* wards. All of them were explored at operation, and in each the right ovary was involved. From the fact that these patients were admitted on the surgical side it is reasonable to suppose that the pre-operative diagnosis was always acute appendicitis, the truth being learnt only after exploration of the abdomen.

It is remarkable that before 1924 not more than two cases occurred in any one year, while in that year five cases occurred within less than three months. The average for the period 1915–24 works out at 1·4 cases admitted on the surgical side per year. The corresponding figure for acute appendicitis during the same period is 582 per year.

During the same decennium ten cases of hæmorrhagic lutein cyst were admitted to the *gynæcological* wards of the London Hospital, the diagnosis being established by laparotomy. In eight of them the left ovary was involved, in two the right. This suggests that the two ovaries are equally affected, and indicates that when the condition occurs on the left side the question of acute appendicitis does not arise.

I am indebted to Sir Hugh Rigby, to Mr. A. J. Walton, and to Mr. Hugh Lett for permission to

publish six of these cases; and also to Prof. H. M. Turnbull, Director of the Pathological Institute of the London Hospital, for permission to make use of the findings of his department.

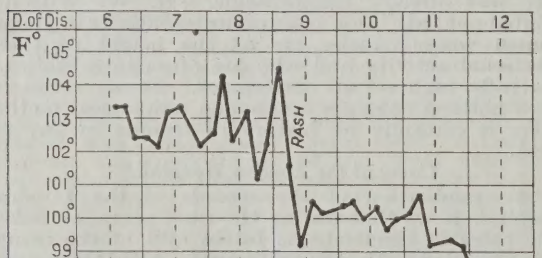
A REPORT ON TWO CASES OF TYPHUS OF AN ANOMALOUS TYPE.

BY ALAN RANDLE, *M.C.*, M.D., B.S. LOND.,
MEDICAL SUPERINTENDENT, ST. PETER'S (WHITECHAPEL) HOSPITAL;
AND
CHARLES MARIAN, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT MEDICAL OFFICER TO THE HOSPITAL.

WE are reporting the two cases detailed below, as an account of this illness seems to be urgently called for in the interests of public health, and in view of the fact that an account such as this may help others should they meet equally puzzling cases.

The man's illness was the first to come under notice, and after a rash appeared it was thought necessary to bring all possible laboratory tests to bear. As these came back one after the other in favour of typhus, it became necessary to notify the disease. Even so, the case presented a startling isolation and an absence of any known ætiology, but

FIG. 1.



Temperature chart in Case 1 from April 30th to May 12th.

Dr. D. L. Thomas, the medical officer of health, has, we understand, discovered some history of dealing in, and storing of, second-hand clothes. This, however, appears to have ceased two years ago. The man's wife was subsequently brought into hospital with an illness presenting the same clinical features as the husband's except that there was no rash, but two tests having come back in favour of typhus, it became necessary to notify her and send her away to the M.A.B. Hospital.

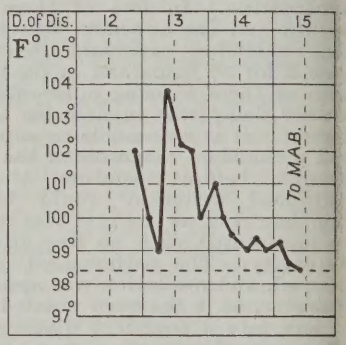
CASE 1.—A. G., aged 48, tailor's machinist, admitted to hospital April 30th, 1928, with a diagnosis of influenza.

History.—Ill five days, with pains all over, but especially complaining of headache and sleeplessness. Worse the last two days, when he was forced to go to bed. In previous good health and no infectious disease at home.

Condition on Admission.—Moderately well nourished. Temp. 103·4° F.; pulse 120. No respiratory distress; tongue coated brown and dry. Pharynx: injected and glazed appearance. Skin: no visible eruption. Lymph glands: no enlargement. Central nervous system: pupils equal and react L and A; no external ocular palsies; cranial nerves normal; all reflexes +; generalised hyperæsthesia; slight rigidity of limbs, but no paralysis. Mental condition: mild delirium; resistive to attention.

Subsequent History.—On the following day the delirium was the most prominent sign, the patient becoming almost maniacal, necessitating his transfer to an observation ward. There was impaired note base of left lung. This state was maintained till May 3rd (ninth day of disease), when the temperature fell to 99·2°. The delirium gave way to a state of profound apathy, the patient lying quite inert, talking being a great effort; it was necessary to catheterise him. He complained of intense frontal headache. At this stage (ninth day) a faint petechial eruption was noticed, confined to the trunk and proximal parts of the limbs, the individual lesions being about one-sixteenth of an inch in diameter. The eruption had faded by May 13th, having never involved the face, forearms, or legs. The pyrexia subsided by May 6th, the twelfth day of disease (see Fig. 1). But there was no improvement till the 15th, when the patient commenced to take an interest in his surroundings, asking for food, and helping himself. His frontal headache did not abate, and on the 21st he complained of seeing double. He had diplopia for distant objects only. There was slight bilateral ptosis and weakness of both external recti. Since then the headache and diplopia have gradually subsided. He is up in the afternoons, his general condition is much improved, the only physical signs present being a monotonous voice and slight immobility of the face.

FIG. 2.



Temperature chart in Case 2 from May 30th to June 2nd, when the patient was removed to a hospital of the Metropolitan Asylums Board.

Urine: Urates, + +; otherwise no abnormal constituents. Ehrlich's diazo-reaction −ve. May 15th: Widal, −ve 1/10, 1/25, 1/50, and 1/100; −ve paratyphoid. Weil-Felix, +ve up to 1/1000 dilution. May 9th: Blood, Hb., 88 per cent.; red blood cells, 4,700,000; white blood cells, 13,000. Differential: Neutrophils, 89 per cent.; lymphocytes, 11 per cent.; hyalines, eosinophiles, basophiles, nil. May 10th: Cerebro-spinal fluid, under pressure + +; clear. Reaction, faintly alkaline. Albumin, 0·06 per cent. Globulin, + +. Fehling, normal reduction. Lymphocytes, slight excess. W.R., +ve (strong).

CASE 2.—K. G., aged 51, wife of A. G., admitted May 30th, 1928.

History.—Confined to bed five days, but not feeling well for seven days before that, complaining of intense headache, especially at the back of the head, and stiffness of the neck, and feeling very hot. Also complained of a recurrence of a cough while she was ill, and that it hurt her to cough.

The *condition on admission* was almost identical with that of the husband. Temp., 103·6° F., very restless and delirious; tongue dry, brown, and cracked. Spitting up very tenacious sputum. There was no rash, and it was decided to await the result of the Wassermann and Weil-Felix tests before notifying this case. However, these both came back positive, and the case was transferred to the M.A.B. on June 2nd. The temperature had then fallen to normal by lysis (see Fig. 2), but the delirium persisted.

The diagnosis of these two cases presented very considerable difficulties, and we should like to acknowledge the help we received from the consulting staff of this hospital, from the medical officer of health, and from the Ministry of Health. The disease which was most likely to cause confusion was encephalitis lethargica, with the pyrexia, headache, and diplopia; but the combination of a delirium, with a subsequent state of complete apathy, coupled with a petechial eruption, positive Wassermann and Weil-Felix reactions, forced on us a diagnosis of typhus. On the other hand, a temperature falling by lysis, absence of rash in the woman, and absence of body vermin in both cases, are rather strong points against this disease.

Clinical and Laboratory Notes.

A FURTHER NOTE ON THE RECORDED INCREASE OF CANCER.

By D. F. Shearer, M.B. Oxf., F.R.C.S. Eng.

It was suggested in an annotation on the Apparent Increase of Cancer in The Lancet of Jan. 28th last that, for purposes of comparison, "a better idea of the general trend of the death-rate" of cancer would be given by taking a group of five years instead of a single year. Acting on that suggestion, the figures for the sites given for the years 1901–05 in the Annual Report for 1925 were standardised on the basis of the population of 1925 and divided into two groups. The one (A) containing the sites: intestines, larynx, lung, pancreas, kidney, bladder, and prostate, was selected as representing those sites in which the greatest increase in diagnostic facilities had occurred during the period; and the other group (B) contained the remainder. Two special groups were also worked out, the buccal group in the male and the sex organs in the female. In the group 1901–05, to the sites mouth, tongue, jaw, and lip was added the site "lymphatic glands of the neck," as practically in all cases cancer of these glands is secondary to one of the primary sites in the buccal cavity group. It is not included in 1925, as it is not stated separately in the list of sites given in that year. This is probably of no importance, as the number of deaths attributed to that site had fallen 70 per cent. by 1912; and more accurate information as to site than was provided by the original certificate was obtained by the Registrar-General in 1925 in over 1000 cases. Presumably, then, all deaths certified as due to cancer of the lymphatic glands of the neck in 1925 were corrected to give the primary site. The figures were worked out for the 10-year age-groups given in the 1925 report, and collected into two groups "35–65 years" and "over 65 years" to save space.

Table showing the standardised figures and rates of increase or decrease in deaths from cancer in the various groupings in 1901–05 and in 1925, and in deaths from "old age" for males, females, and persons.

Males.

Sites.	35–65 years.			Over 65 years.		
	1901–05.	1925.	% inc. or dec.	1901–05.	1925.	% inc. or dec.
All	10,082	12,241	+ 21	7,213	11,155	+ 54
(A)	1,642	3,698	+125	1,298	3,542	+172
(B)	8,440	8,543	+ 1	5,915	7,613	+ 28
Buccal ..	1,625	1,442	− 10	1,023	1,184	+ 15
"Old age"	..	..	..	19,320	10,063	− 48
Females.						
All	15,981	14,953	− 4	9,924	12,372	+ 24
(A)	1,830	2,281	+ 25	1,532	2,801	+ 82
(B)	4,151	12,672	− 10	8,392	9,571	+ 14
Sex organs	7,390	7,007	− 5	3,056	3,528	+ 12
"Old age"	..	..	..	28,708	14,980	− 48
Persons.						
All	26,063	27,194	+ 4	17,137	23,527	+ 37
(A)	3,472	5,979	+ 72	2,830	6,343	+121
(B)	22,591	21,415	− 5	14,307	17,184	+ 20
"Old age"	..	..	..	48,028	25,043	− 48

inc. = increase; dec. = decrease.

The figures show that both in males and females, up to the age of 65, the whole of the increase is attributable to the small group (A); that over that age there is a second factor at work which affects both (A) and (B); and that after allowing for an increase in group (A) over the age of 65 at a similar rate to that obtaining below 65, there is an increase in the males of 2320, and in the females of 2065, against reductions in the deaths assigned to "old age" of 9257 and 13,728 respectively. These figures correspond to some extent with the proportions which deaths from cancer at this age-group bears to deaths from all causes. It is not to be expected that the correspondence would be exact, but it is sufficiently close to be extremely suggestive of a near relationship between increasing cancer and decreasing "old age" deaths. It is curious to note that the two groups, buccal in the male and sex organs in the female, which are undeniably "accessible" and have not been subjected to any increase of diagnostic facilities, show no increase whatever. The figures of the former are 2648 and 2626, and of the latter 10,446 and 10,535.

There is, however, another factor in the apparent increase of cancer to which, as far as I know, attention has not been directed, and it may conveniently be stated in the form of a logical syllogism.

Death from some cause is inevitable.
Death from causes other than cancer is not inevitable and can be prevented, and the rate is diminishing.
Therefore death from cancer is inevitable and its rate must be increasing.

It is quite obvious that if the chance of subsequent death from cancer at any given age is a, and of subsequent death from all other causes is b, then, since $a+b$ must equal unity. a must increase as b diminishes. But this does not mean that the chance of death from cancer at any given age is increasing; there is sound reason to believe that cancer is not a pathological entity, but a physiological process with a more or less fixed rate for each age; it merely means that the individual has a greater chance than formerly of surviving to an age where the death-rate from cancer is higher. It is impossible at present to estimate how far this factor is operating in the recorded increase of cancer in later years, but there can be no doubt whatever that its effect will be seen in the future.

It may seem pessimistic to assert that the fruition of all our efforts for the preservation of health and the prevention and cure of disease and accident can only lead to universal death by cancer, but it must be remembered that in the earlier years of life cancer can be eradicated and that in the very old it frequently, if not invariably, assumes an almost benignant type which quite clearly often in the past has been, and not seldom in the present is, mistaken for senile decay.

A CASE OF PERICARDIAL KNOCK ASSOCIATED WITH SPONTANEOUS PNEUMOTHORAX.

By W. A. Lister, M.B. Camb., M.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

The term "pericardial knock" was applied during the war to a sharp, rapping sound which was sometimes to be heard over the præcordium in cases of gunshot wounds of the chest, and was often sufficiently loud to be audible at a distance from the patient.

The first to draw attention to the phenomenon were Rees and Hughes,[1] who quoted nine cases from their experience. Shortly afterwards Maynard Smith [2] described its occurrence in some of his cases on the Western front, and Henley Munden [3] recorded a case in a boy who was shot in the chest while rabbiting. Hull [4] mentions it in his book on war surgery, and there is also a brief account of the condition in Norris and Landis's text-book on diseases of the chest.

Though the sound varies in intensity in different cases, and persists for a variable period after the original injury, all the cases recorded present certain

[1] Rees, W. A., and Hughes, G. S.: The Lancet, 1918, i., 55.

features in common. In character the sound is a sharp, hollow knock; it is always systolic in time and usually varies with respiration, being loudest during inspiration, though the case described by Henley Munden did not show this variation. Finally, it is always associated with a wound of the left side of the chest. A number of suggestions have been put forward to account for the sound. Rees and Hughes thought it possibly might be caused by vibrations imparted by the cardiac impulses to a column of air enclosed in a bronchus by a missile or blood-clot. Maynard Smith suggested that it was due to air which had found its way into the interstitial tissues of the lung or mediastinum. In civilian practice the condition appears to be somewhat of a rarity, and it has not been possible to find any record of its occurrence apart from gunshot wounds of the chest. The following case therefore seems worth recording:—

History.

A commercial traveller, aged 31, was first seen on Feb. 1st, 1928. He complained of slight pain in the region of the second left intercostal space and of a loud tapping sound in his chest. He stated that six days previously, while sitting in a tramcar he had experienced a sudden, sharp pain in the left upper part of his chest and had felt faint and breathless for a moment. He got out of the tram, and after obtaining a little brandy from a friend who lived near by, he returned home and went to bed as the pain persisted, though he felt quite well in other respects. For the next two days he remained in bed and the pain rapidly passed off except for a slight tenderness. On the third day he decided to get up, but on putting his feet to the ground he was horrified to hear a loud rapping sound in his chest which was also plainly audible to his relatives. Accordingly, he returned to bed and the sound ceased when he lay down. Next day he made another attempt, and though the sound returned as before as soon as he stood up, it caused him no inconvenience and he remained up and about and was able to walk round for the consultation two days later without experiencing any ill-effects whatever.

Previously he had been healthy, though he recognised that he was a nervous man. At no time had he suffered from pleurisy or cough, nor so far as he knew had he lost weight. There was no history of tuberculosis in the family.

Physical Signs.

On examination the patient was thin, pale, and nervous, with a spasmodic tic of the right side of the face. Pulse 116 per minute, regular. Temperature normal. As he sat giving the history of his illness at a distance of some 5 feet a hollow knocking sound could easily be heard coming from the patient's chest. Its point of maximum intensity was found to be situated over the fourth left costal cartilage, and a sharp tap corresponding to the sound was felt on palpation over the sternum. In character the sound was very similar to that heard over the brachial artery when taking a blood pressure at the point when the diastolic pressure is approached, but was, of course, very much louder. It was mid-systolic in time, coming at the end of the first sound and separated from the second sound by a short but distinct interval. It varied both with posture and with respiration. In the prone position it disappeared entirely; on sitting up it became clearly audible towards the end of expiration, but grew fainter and finally ceased as the lungs expanded. When the patient stood up the sound was at its loudest, rising to a maximum at the end of expiration and diminishing with inspiration. A deep inspiration could stop it entirely, even in the upright position, but ordinary quiet breathing did not do so. In other respects the heart sounds were perfectly normal, and the blood pressure was 145 systolic and 90 diastolic.

There was slight tenderness on pressure over the second left interspace in the midclavicular line, and the left side of the chest presented the usual signs of a pneumothorax with slight displacement of the heart to the right, so that the right margin of cardiac dullness was ¼ inch to the right of the right sternal border, and the apex only 3 inches from the mid-line. The coin sound could not be elicited, no succussion splash was heard, nor was a metallic quality added to the pericardial knock which was audible all over the chest.

A radiographic examination on the fluorescent screen showed the lung to be separated from the chest wall by 1 inch in the lateral plane, and there was also air surrounding the apex and base and lying between the upper half of the lung and mediastinum as far down as the reflexion of the pleura at the hilum. The whole lung, therefore, in a partially collapsed condition hung loose in the thorax suspended from the hilum. It was kept in constant flicking movement by the beating of the heart so that its free lower margin continually agitated the surface of a small quantity of fluid that lay in the costo-phrenic angle. Owing to this constant movement it was not possible to obtain a sharply defined radiogram of the outline of the lung.

During the course of the next fortnight the knock became fainter and less frequent, finally to disappear three weeks after the onset of the pneumothorax. At the end of this period I again examined him and aspirated half a pint of slightly turbid, straw-coloured fluid from the left base. It contained numerous leucocytes and gave the rather unusual differential count of: eosinophils, 95 per cent.; lymphocytes, 2 per cent.; endothelial cells, 2 per cent.; neutrophils, 1 per cent. No tubercle bacilli or hooklets were found and the culture was sterile.

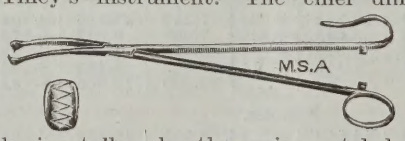
Six weeks after the onset of the illness there were no abnormal physical signs in the chest except for slightly diminished movement at the left base. A radiogram taken at this time showed a slight excess of fibrosis with a few scattered small foci of calcification spreading out from both hila, particularly the left. No signs remained of the pneumothorax or effusion. Treatment throughout was based on the assumption that the underlying cause was a ruptured tuberculous focus, and the patient improved in general health and gained weight during the time he was under observation.

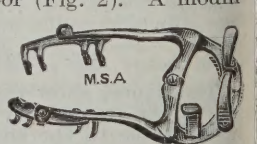
Since there was no trauma in this case it is unlikely either that air was present in the interstitial tissues of the lung or mediastinum or that it was locked off in an occluded bronchus. Bearing in mind the character of the sound, the fact that it was precisely systolic in time, and that its point of maximum intensity was directly over the root of the left lung, it would appear possible that it is analagous to the sounds heard when estimating the blood pressure by auscultation and that it arises in the left pulmonary artery. Partial obstruction of this artery at the hilum by tension or distortion caused by displacement of the lung appears not unlikely, and, as the position of the lung would vary with the posture of the patient and with the respiration this would also account for the variations in the sound observed in this case. But if this is the right explanation of the production of the sound it is curious that it is not more often observed.

New Inventions.

MODIFIED FORCEPS AND RETRACTOR.

I SHOULD like to call attention to two instruments which have recently been modified by me, and which have been appreciated by several leading surgeons: (1) Tonsil Vulsellum Forceps (Fig. 1), adapted from Tilley's instrument. The chief difference is, that while the jaws have a similar curve they grasp the tonsil longitudinally instead of horizontally, also the spring catch has been replaced by the ordinary "cross over" shanks, which are fitted with a ratchet at the handles, by means of which a good grip is retained throughout the operation. The instrument has been considerably lengthened, being 9½ in. as against the 8 in. of Tilley's. The bows of the forceps are so made that a snare can easily be applied. (2) Mastoid Retractor (Fig. 2). A modification of Wagener's, giving a wide field, the shanks being bent to allow of this. The base of the instrument is curved so as to lie well back out of the field of operation. It is opened and closed by a ratchet action, which is easier and quicker in use than the ordinary screw.





These instruments are sold by the Medical Supply Association, Gray's Inn-road, W.C.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

AT a meeting of this Section held on June 6th, Mr. WARREN LOW, the President, took the chair, and a paper on

HARE-LIP

was read by Dr. VICTOR VEAU (Paris). He demonstrated a large series of lantern slides, setting out the principles upon which his operations for the deformity were done. He had been interested in the condition, he said, for 30 years, during which time he had performed more than 1000 operations for it, and also had minutely studied over a hundred cases which had been operated upon by others. He had made many mistakes, and when he did not secure the results aimed at he did his best to ascertain what was the reason. The causes of the malformation he did not expect to find.

Clinically hare-lip could be subdivided into four forms. The first was unilateral simple hare-lip, which constituted about 30 per cent. of the cases. The second, and most common, form was unilateral total hare-lip, accounting for about 40 per cent. of the total cases. The third and rarest form was bilateral simple hare-lip, these forming only about 5 per cent. Lastly, there was the bilateral total hare-lip, which were about 25 per cent. In unilateral simple hare-lip there were all the elements for reconstitution to form a quite normal lip on the inside edge of the cleft, but the muscles were lacking, and this was the deficiency that caused most of the trouble. After having tried a variety of incisions and forms of operation, he had come to the conclusion that the most important step was suture of the muscles, for it was this that imparted to the lip the thickness and protrusion which were so necessary for a good cosmetic result. Then the operator could direct his attention to the exact adaptation of the cutaneo-mucous lining. He used a very fine, straight needle threaded with silk, and to be sure of securing direct coaptation he used magnifying glasses in the form of spectacles. The suture was finished on the cutaneous side and on the mucous side. His object in making a flap was to secure that protrusion of the lips; every effort was made to constitute what was popularly termed "Cupid's bow."

Dr. Veau's photographs showed that a month after operation the line of incision was still plainly evident, but six months afterwards, in many of the examples, neither scar nor line could be detected, the reason being, he said, that he did not put the stitches needlessly deep. A scar resulted when mucous membrane was included in the suture. This was the mistake most commonly made by surgeons who did not exercise sufficient care in the operation for hare-lip. In some of the cases after operation an island of mucous membrane was to be seen in the skin; it always remained bright red, never became transformed into skin, and to a woman was a disfigurement. Another error was to leave an irregular muco-cutaneous line. Great care must be taken over the suture of the muscles, to give that protrusion and correct line which would make the lips approximate to the normal. Many of the errors made were capable of being remedied by further operation if parents, and the patients themselves, would permit it.

In unilateral total hare-lip of severe degree, with a very wide cleft, the lip could not be reconstituted by operation. In older children the first step which was often necessary was for the dentist to straighten the incisor teeth. In one variety of unilateral total hare-lip there was no cleft palate; these, he considered, constituted about 12 per cent. of all cases, and they were very difficult to treat. In dealing with unilateral total hare-lip his object was to avoid two bad results. One was retraction of the upper lip the other was flattening of the nostril. When the lower lip was more prominent than the upper, the result was unsightly. For operations on hare-lip the surgeon should have a mentality different from that required for hysterectomy or amputation of a limb, because of the minuteness and delicacy of the manipulations of tissue required. He turned up a mucous flap from the septum; it was easily separated; this flap was very tough and did not break. It was separated as far as the anterior part of the tubercle. The difficulty was in the ridge. He cut the frænum of the upper lip, and completely separated the palatine mucous membrane, preserving the posterior palatine artery. He first reconstituted the floor of the nose, as it was then easier to reconstitute the palate afterwards. The horizontal flap must be the threshold of the nostril.

Difficulties of Operation.

Mr. C. H. FAGGE said he was unable to bring forward anything like such a wealth of material as Dr. Veau had done; his purpose was, rather, to set forth a few of the difficulties of operation in these cases as they had presented themselves to him. Hare-lip, he considered, could be divided into three degrees: (1) partial; (2) unilateral; (3) bilateral. It was part of his thesis that in every case the tissues might be defective. Some surgeons thought the tissues were fully developed and were simply separated. Even when the first degree of hare-lip was present there was, in his experience, an abnormality of the ala, which must be dealt with. He had always found that in those cases incision had to be carried up into the nose, so as to bring the ala inwards.

The first difficulty was to scale out the ala. This could be done by undercutting the cheek on the affected side. Provided the tissues of the cheek were separated from the maxilla far enough upwards, even to the outer canthus of the eye, the ala could be brought into its natural position. If that was done the naso-labial fold would be restored. The next difficulty was the formation of a normal nostril. In his experience, this demanded that something should be cut away, usually from the inner side of the cleft, so as to convert what was an abnormally wide nostril into one of ordinary size. On the other hand, it was possible to cut too much away and leave the child with too narrow a nostril instead of a very wide one. A very wide nostril caused difficulties in speech, because too much air came through it; if it was associated with a defect in the palate, it made the pronunciation of certain letters very difficult. In one case, which he described, the defective speech due to the nostril being very wide had necessitated a second operation, involving an extensive dissection of the cheek.

He had not found that restoration of the lip was, in itself, very hard; but there was one difficulty connected with the ala which he was at present unable to overcome—namely, its eversion. Even when brought into the normal position, the ala, in these children, was inclined to be everted, whereas the normal ala was inverted. He would like to know how other members of the Section had dealt with this difficulty. He had only been able to excise a portion of the cartilage on the outer side of the nose so as to turn it inwards, but had not had any great success. Another difficulty was that due to depression of the apex of the nostril; it was very difficult to bring it into a normal position. For some time he had given up cutting through the muco-cutaneous surface. He carried the incision three-quarters of the way through the lip, then turned back the cut flap and sutured it behind the tissues of the lip itself, so as to preserve a wide mucous surface behind, which would prevent adhesion of the lip to the alveolus. On the larger fragment there was always an area of mucous membrane carried upwards in the line of what should be the tubercle, and this must be carefully removed. In reconstituting the lower margin of the lip the chief difficulty was the formation of a good tubercle. The lip should have

no adhesion to the alveolus; it must be quite free, so that it would come forwards with each movement of the remainder of the face.

The complete and the bilateral cases presented no difficulties apart from those he had spoken of. Beyond the plastic portion of the operation, he had confined himself to the continuous suture through the deep structures, including the muscles on both sides, using a cutaneous suture of fine gut, and in most of his cases this lip operation had been done at the same time as that on the cleft palate—when the latter condition was present—usually at the age of about three months.

The Need for Secondary Operations.

Mr. T. POMFRET KILNER gave a description of the work of Mr. Harold Gillies and himself in this region of plastic surgery, largely in doing secondary operations in cases in which the first had not been satisfactory. He put forward a plea for simple primary reconstruction. However small the parts, each element of the lip had its separate and distinct layers, and these, especially the muscular layers, must be correctly approximated if proper balance of function was to result. In all plastic work the amount of raw surface must be reduced to a minimum, as raw surface meant scar tissue and subsequent contraction. He considered that no surgeon was justified in promising a perfect cosmetic result in these cases as a result of only one operation; his chief aim should be to give establishment of function, and for this reason all zig-zag procedures and flaps were to be condemned. One ought to concentrate on the nostril. Mr. Gillies and he never tried to equalise the sides of a cleft by elongating the shorter of the two elements; the longer of the two sides required shortening in order to give a good cosmetic result. In the operation no skin and very little mucous membrane was sacrificed. In unilateral cleft cases Mr. Gillies frequently turned over a much smaller flap of muco-periosteum from the stump of the alveolar process on the longer side. Mr. Kilner expressed his admiration of the work of Ritchie, of Minnesota, in this kind of surgery. Ritchie got very accurate muscle approximation, and made use of electrical stimulation to ascertain the upper and lower limits of each muscle concerned. In the practice of his colleague and himself, the stitches were removed in from three to five days, and they preferred to have a slight gaping of the wound. Great improvement of contour was found to result from the use of the epithelial inlay. In most of the cases which came for a second operation for readjustment of the lip the skin triangle had been incorporated too low down. In some patients a reduction of nose was called for, and some noses could only be dealt with adequately by fracturing and resetting certain bones. Dealing with the nasal septum often resulted in the solution of difficulties which had resisted all other measures.

SECTION OF OPHTHALMOLOGY.

AT a meeting of this Section held on June 8th Mr. ERNEST CLARKE, the President, took the chair, and a paper entitled

THE ANTIBACTERIAL BODY LYSOZYME

was read by Mr. FREDERICK RIDLEY.

Lysozyme, described by A. Fleming in 1922, was, he said, an enzyme which could destroy most of the organisms which were pathogenic for man and the lower animals. It was very widely distributed in nature, being found in all animal tissues and tissue fluids and in most of the secretions. In tears, polymorphonuclear leucocytes, nasal mucus, and the sputum of man it was present in very high concentration, therefore it was difficult to over-estimate its importance in protecting the individual against bacterial invasion. It was destroyed by temperatures above 75° C., it acted most rapidly at 60° C., and was very efficient at the temperature of the body. The enzyme was destroyed by free acid or alkali. It disappeared on intravenous or subcutaneous injection into an animal. Wolff regarded the fixation by fats as the probable natural means of storage of the enzyme in the body. It was present in turnips, white of egg, fowl, and fish. In man it was present in greatest concentration in leucocytes and cartilage, in tears, nasal mucus, and sputum. Mr. Ridley showed on the screen many plates to prove the strong bactericidal power of lysozyme. Fleming and Allinson had first showed that the blood serum contained lysozyme, and that in polymorphonuclear leucocytes it was present in very high concentration. The lysozyme content in tears was tested in more than 100 cases. In 16 cases of conjunctivitis, acute and chronic, the infected eye was found to have a reduction of lysozyme to about 30 to 60 per cent., the unaffected eye having a normal titre.

As to the general causes of lysozyme reduction, Finlay observed that in growing rats which were deprived of vitamin A kerato-malacia developed, and this was associated with a fall of lysozyme in the tears. He further made the valuable observation that the introduction of a drop of human tears into the conjunctival sac from time to time postponed that condition. In six cases of phlyctenular disease, and four of recent interstitial keratitis, the lysozyme titre of both eyes was less than 55 per cent. of the normal, even though only one eye was affected, probably because of the associated general ill-health. This perhaps accounted for both eyes being attacked. The reduction of lysozyme in the normal eye in keratitis was seen in several cases having positive signs of congenital syphilis, and was not observed in this case which showed no signs of congenital syphilis. Thus it was conceivable that the interstitial keratitis was due to a local infection other than by the spirochæte. Epiphora was associated with a fall in the lysozyme titre in every case observed, and when the epiphora ceased the lysozyme titre rose at once and there was clinical improvement in the condition of the eye. It was evident that the lacrymal gland must be partially paralysed by the instillation of atropine into the conjunctival sac.

Mr. Ridley said that a teaspoonful of the pure enzymic substance would confer its characteristic power over *Micrococcus lysodeicticus* upon 100 million gallons of normal saline. No antiseptic which had been tested compared with lysozyme in its power to inhibit the growth of this organism. As lysozyme was tolerated by the tissues, without appreciable reaction in concentrations as great as 40 times that in tears, the possibilities of its application for superficial and generalised infection were obvious. But the preparation of the enzyme in a pure state presented many difficulties, and demanded a laboratory equipped specially for the purpose.

Dr. ALEXANDER FLEMING commented on the fact that the substance was found in the parts of the body where it was wanted: in the nose, in the sputum, and the parts exposed to microbes in the air. He supported Mr. Ridley's contentions, and said that his observations on the clinical conditions observed carried the subject a distinct step forward. Wolff, in Holland, had isolated the substance from egg-white, and this opened up a means of obtaining it in a very concentrated form.

Mr. LESLIE PATON said this research started from an attempt to determine the action of herpetic viruses, and it was a matter of congratulation that Mr. Ridley had been induced to carry on this important work. He (Mr. Paton) had suggested some years ago that the absence of this substance might be one of the causes of neuropathic keratitis developing in some cases. He thought that after the Gasserian ganglion had been destroyed, or the nervous supply to the lacrymal gland had been ablated, the tears might not show the same concentration of this—as it then was—newly discovered substance. He hoped Mr. Ridley would also be able to inquire into the question of neuropathic keratitis and the herpetic viruses.

Colonel A. E. LISTER spoke of the irritant action of mercuric chloride as a preventive of dirty eyes in

connexion with cataract operations. It caused lacrymation, and he asked whether an effect of this was to reduce the lysozyme in the tears.

The PRESIDENT spoke highly of the value of this far-reaching paper; it had a direct practical application to many diseases, and he hoped the research would be continued.

Mr. RIDLEY, in reply, said it was impossible to get tears in any considerable amount from the eye in a condition in which the trigeminal nerve was damaged, but such secretion as did then exist in the eye contained some lysozyme. Dr. Fleming's researches on the direct action of antiseptics on lysozyme showed mercuric chloride to be very damaging. The increase of epiphora where epiphora was already present must be to the considerable detriment of the patient.

Reports of Cases.

Mr. NORMAN FLEMING showed a patient with a congenital anomaly simulating retinitis proliferans. A band of fibrous tissue stretched from the disc in the lower part of the fundus and seemed to be adherent to the fundus. There had been no injury at birth nor since.

Mr. J. D. M. CARDELL showed a case of arborescent cataract; and Mr. HUMPHREY NEAME one of iridocyclitis in a man aged 41. In the right eye was a deep striation, and in the left fine keratitis punctata.

Mr. MONTAGUE HINE related a case in which an artificial eye which had accidentally burst in situ was removed only with considerable difficulty. He said that spontaneous fracture of the cheaper kinds of glass eye was not uncommon, as they were not properly annealed in a warm sand bath after being blown, but it must be rare for the contact of the eye with the socket to be so close that some of the orbital tissue was drawn into the eye and strangulated, as in the present instance. This woman felt something explode in her face, but was unable to remove the artificial eye, and had increasing pain. The house surgeon at the ophthalmic hospital could not remove the eye either, and Mr. Hine was asked to see her. He gave her an anæsthetic and passed a bent probe up the back of the eye from below. This pushed aside the tissue which was blocking the hole at the back and let in the air, and the eye was released at once. The absent piece of glass was inside the eye, emphasising the fact that there was a negative pressure originally in all blown eyes. Mr. Hine also reported a case of neurofibromatosis, and showed histological slides from it. The eye was useless as an organ of vision, and both lid and eyeball were removed. The pathological report by Mr. Hervey Wyatt was read.

Mr. F. A. JULER reported a case of his own of the same nature, and Mr. TREACHER COLLINS described the findings in the cases of the kind he had examined.

Reviews and Notices of Books.

DEVELOPMENT OF THE HUMAN EYE.

By IDA C. MANN, M.B., B.S. Lond., F.R.C.S. Eng., Assistant Surgeon, Royal London Ophthalmic (Moorfields) Hospital. With a Foreword by Sir JOHN HERBERT PARSONS. London: Cambridge University Press. Published for the *British Journal of Ophthalmology*. 1928. Pp. 306. 36*s*.

"Miss Mann has been peculiarly fortunate in having access to what is probably the most comprehensive series of human embryos available in this country."

So says Sir John Parsons in a foreword to this work. She has used this material placed at her disposal by Prof. J. Ernest Frazer to the utmost advantage, and the result is a monograph which depicts the processes which constitute the development of the human eye with a wealth of detail and illustration which has never before been attempted. The fact that the directors of the *British Journal of Ophthalmology* have come forward to undertake its publication is in itself a high testimonial to the scientific importance of the work and to the value of the beautiful plates drawn by the author which enrich its pages.

The first two chapters are devoted to development from the first appearance of the embryonic plate until birth. The part played by surface ectoderm, neural ectoderm, and associated mesoderm are distinguished. Incidentally congenital malformations, microphthalmia, congenitally cystic eyeball, and coloboma of the retina are explained. The next chapter deals with the lens and certain congenital abnormalities in this organ which are shown to have relation to developmental defects. No defect can be congenital if it is situated outside the "fœtal nucleus." On the other hand, certain defects may arise in postnatal life and yet be developmental, since the lens continues to develop throughout life. In the next chapter, on the "Neural Ectoderm," the development of the different layers of the retina is described with a great wealth of illustration and detail. The problem of the origin of the vitreous is a very obscure one, on which the last word has not yet been said. A distinction is drawn between the 'primary vitreous" derived from both lens-plate and optic vesicle and occupying the region of Cloquet's canal, and secondary or adult vitreous derived, in part at any rate, from the mesoderm, which enters the optic vesicle through the fœtal fissure. It is impossible to say of any given vitreous fibril how much of it is mesodermal and how much ectodermal. The suspensory ligament of the lens is derived from fibres which arise during the latter part of fœtal life and which have been called the tertiary vitreous. Under the heading of "Associated Mesoderm" are described the development and arrangement of the larger blood-vessels in the orbit which supply or drain the optic cup; also the development of the choroid, the development and retrogression of the fœtal intra-ocular blood system—i.e., the hyaloid artery, the tunica vasculosa lentis and their connexions—and the differentiation of the vessels of the iris and ciliary body; and, lastly, the development of the retinal arteries and veins. The ciliary muscle and region of the corneo-scleral junction (sections of which show well the "scleral spur" first described by Prof. Arthur Thomson) are illustrated by several drawings and diagrams. A full account is given of the development and subsequent atrophy of the pupillary membrane. The vessels atrophy as far back as the first anastomotic arcade where the arteries and veins are continuous; this so-called "circulus arteriosus iridis minor" is more correctly termed "circulus vasculosus iridis minor." It is of some interest to learn that in the sclerotic condensation that produces the sclera there is a lagging behind of the process in the posterior region. The author is too cautious to make anything more than a mere suggestion, but the inference cannot be avoided that this fact may have something to do with progressive myopia, for presumably, in certain stocks, the process of condensation is liable to be arrested too soon. The latter part of the book deals with the extrinsic ocular muscles, the lids and lacrymal apparatus, and the position of the eyes. In the final chapter the structure of the retina is compared to that of the cerebral cortex; up to the fourth month of development the analogy is close. Finally, Miss Mann supplies a synoptic comparison of optic with general development, and the volume ends with a large bibliography.

It is possible that the appeal of this work at present may be limited, but it will certainly be international Apart from its value to embryologists and biologists, which is undoubted, it should prove also of use to those practising ophthalmologists in all countries who are interested in the scientific side of their specialty.

Those eager to apply to clinical problems the results of developmental studies will find in it a fruitful source of inspiration, and will be grateful for the originality and vigour with which Miss Mann has attacked the subject which she has made her own.

RECENT ADVANCES IN TROPICAL MEDICINE.

By Sir LEONARD ROGERS, C.I.E., M.D., B.S. Lond., F.R.C.P., F.R.C.S., F.R.S. London: J. and A. Churchill. 1928. With 12 illustrations. Pp. 398. 12*s.* 6*d.*

IN tropical medicine, detailed work, no doubt of varying degree of accuracy, comprehensiveness, and interest, is reported almost weekly, and in ever-increasing volume. Of recent years new journals devoted to tropical diseases and new medical journals in the tropics have appeared; and abstracts of work in every field of medicine from every part of the tropics are published periodically in the *Tropical Diseases Bulletin*. Sir Leonard Rogers declares this publication a boon to the great majority of medical men in the tropics, far away from libraries, and acknowledges his own indebtedness to its abstracts for much of the information here summarised. He supplies an interesting and detailed précis of much recent work on some 23 tropical diseases. In some of them his own contributions have advanced knowledge, to the relief of human suffering and the added power of man over his tropical environment. His selective judgment of what is recent and what is advance will therefore receive wide attention. Yet readable and helpful as is much of this book, it fails in some sections. For example, ankylostomiasis, a minor disease of the white man, ranks hardly below malaria as a major disease of the races native to the tropics. Some of the recent work on this subject is not correctly reported or interpreted. Though this book is dated 1928, there are no references in this section later than 1926; references to Clayton Lane's important researches on diagnosis do not go beyond 1923; and it is disappointing to find that the author does not condemn the stupid dictum that mild infestations with hookworm are of no importance, and that "healthy" carriers may be disregarded! For the rest, treatment in the selected group of diseases is adequately dealt with; the historical sections are very interesting, there are 12 illustrations, and a good index.

NERVE TRACTS OF THE BRAIN AND CORD.

Anatomy; Physiology; Applied Neurology. By WILLIAM KEILLER, F.R.C.S. Edin., Professor of Anatomy and Applied Anatomy, University of Texas. New York: Macmillan Company; London: Macmillan and Co. Pp. 456. £1 15*s.*

A FREQUENT criticism of the medical curriculum of to-day is to the effect that no regular courses of "applied" anatomy or physiology exist; that these subjects are taught without much hint of their further application and are to a considerable extent forgotten by the time the student commences clinical medicine or surgery. Prof. Keiller makes a brave attempt to minimise this defect by writing three books in one for the student of neurology, who is led on by easy gradations from pure neuroanatomy through neurophysiology to clinical neurology. Whether his effort conduces to readiness of absorption by the student of this rather rich and in any case somewhat indigestible pabulum may be open to question. The anatomical part consists largely of a description of the structures seen on cross-section at various levels through the cord and brain-stem, so that, while projection-systems are fully detailed, association-systems in comparison are rather ignored. This is to some extent compensated for in the sections on neurophysiology, afferent and efferent systems being discussed and the special senses examined. The largest division is concerned with applied neurology, and this includes sufficiently accurate accounts of the semiology of lesions involving the anatomophysiological mechanisms described in the other parts of the book. The long supplement devoted to the classification of nervous diseases on an anatomical basis tends to descend to the level of a mere catalogue, so much so that some of its paragraphs really convey little information worthy of the name. Thus: "Familial periodic paralysis, of the flaccid type, occurs in youth after severe nervous strain. It disappears spontaneously, but tends to recur." Other statements unfortunately require emendation—e.g., that a "chronic" form of progressive lenticular degeneration occurs "without cirrhosis of the liver." Yet taken as a whole there is much for the student to learn which is offered him here in clear-cut fashion and with a justifiable dogmatism on his teacher's part. The diagrammatic illustrations, mainly collected at the close, are mostly too sketchy; others are so crowded with anatomical data as to become confusing. Few, if any, of the clinical drawings and photographs seem to be original.

THE NORMAL CELLULAR STRUCTURE OF THE CEREBRAL CORTEX.

L'architecture cellulaire normale de l'écorce cérébrale. By Dr. CONSTANTIN V. ECONOMO, Professor of Psychiatry and Neurology in the University of Vienna. French edition by Dr. LUDO VAN BOGAERT, Agrégé at the Université Libre of Brussels. Paris: Masson et Cie. 1927. Pp. 183. Fr.80.

THIS beautifully printed atlas of the cerebral cortex on its cellular side is a derivative of the much larger volume entitled "Die Cytoarchitectonik der Grosshirnrinde (1925) of the same author, with the collaboration of Dr. Koskinas. Recent though the latter is, the book under review is not a mere abridgement, but contains some 46 new photographic reproductions of cortical fields, as well as fresh considerations derived from further anatomical study. In point of fact, it is really more desirable for the neurologist and neurological student than its predecessor; it furnishes them with a basis of exact information from which they may proceed to further research. Here is to be found a lucid description of structural variations in different parts of the cortex, of differences in thickness, cellular composition and arrangement, of comparisons between one hemisphere and the other, of modifications attributable to age, race, degree of intellectual attainment, of defects found in a number of different pathological conditions (e.g., the congenitally blind, deaf-mutes, oligophrenics). Apart from the microphotographs, a number of diagrams illustrate with clearness and precision the groundwork on which such pathological investigations are based.

For the specialist the volume is indispensable; to him its appeal is direct and immediate.

DIETS FOR INFANTS AND CHILDREN.

Clinical Pediatrics. Edited by Prof. R. S. HAYNES, M.D. Vol. XII. *Infant and Child Feeding.* By H. B. WILCOX, M.D. London and New York: Appleton and Co. 1928. Pp. 202. 16*s.*

THIS unit of Prof. Haynes's admirable system of pædiatrics is likely to be one of the most useful and popular of the series, being devoted to a subject of such universal importance. The author's aim has been to present a clear account of the essentials of the physiology of nutrition, and to explain their bearing upon the problems of infant feeding. His object has been achieved with a considerable degree of success, and the book can claim to provide the student and practitioner with a system of infant feeding which, while based on physiological principles, is by no means as complicated as many of its kind. As a general rule, simple dilutions of fresh cow's milk with added carbohydrate are recommended in the feeding of normal infants when breast feeding is

not practicable. Special measures for the treatment of premature infants and of alimentary disorders are shortly described. The section on breast feeding forms a valuable feature of the book. The author stresses the importance of observing and recording the weight of the mother as well as of the infant, and discusses the deductions which may be drawn from the relation between the two weight-charts.

In one respect the title of the book is somewhat misleading; the diet of the child past infancy is hardly considered.

Die Ernährung Gesunder und Kranker Kinder. Second edition. By E. NOBEL, C. PIRQUET, and R. WAGNER. Vienna: Julius Springer. 1928. Pp. 160. RM.12.0.

THIS work, in which the Pirquet system of nutrition is applied to the practical feeding of healthy and sick children, has undergone some revision and amplification. In the first chapters the essentials of the theory are briefly set out and the nomenclature explained. As is now well known, the theory is based upon the hypothesis that the nutritional requirements of an individual stand in relation to the square of the sitting height (the "Siqua") rather than to the weight. The unit of nutritional value used is the "Nem" (Nährungs-Einheit-Milch), or amount of energy generated *in the body* by 1 g. of human milk. The requirements of the individual are reckoned in terms of a unit which represents one-tenth of the product of these two figures. The accounts here given of infant feeding and of the treatment of nutritional disorders are based on this method of calculation. Little importance is attached to the balance of carbohydrate and fat, provided that the latter is present in sufficient quantity to provide the necessary fat-soluble vitamins. The book has its limitations for the English reader, since Prof. Pirquet's system has made little headway in this country, and is unlikely to become the basis of practical dietetics. In fact, although it can probably claim the highest place from the standpoint of mathematical exactitude, the advantages of adopting so complicated a system are doubtful. However, the volume contains much that will interest those who make a study of nutrition and dietetics, especially the accounts of the treatment of various nutritional disorders.

EUGENICS.

La question eugénique dans les divers pays. By Dr. MARIE THÉRÈSE NISOT. Vol. I. Brussels: Librairie Falk Fils. 1927. Pp. 513.

IN this book Dr. Nisot has presented to those interested in eugenics and the problems allied to it a detailed and scholarly account of the social processes which in recent years have directed attention to this subject. In Great Britain, France, and the United States, which are dealt with in this volume, these processes have much in common. The rapid multiplication of socially useless types, the ravages caused among the best elements of the community by the war, and the relatively great fall in birth-rate of the better-endowed classes, are phenomena common to these three countries. Particular to England is the problem arising from her apparent numerical over-population, and to France and the United States the problem of regulating immigration. Dr. Nisot also discusses the remedies which have found favour in these countries. These remedies are variously calculated to increase the fertility of the socially valuable classes and diminish that of the dependent, hereditarily diseased, defective and delinquent classes, to regulate the process of immigration so that the quality of the national stock will not be impaired, and to promote interest in the eugenic aspects of marriage. Finally, the author reviews in considerable detail those legal enactments of Great Britain, France, and of the different States of the U.S.A. which bear upon eugenics, and describes the aims and scope of the eugenic institutions and publications of these countries.

The book is brought up to date to the end of 1926, and should prove very valuable to medical men anxious to gain a bird's-eye view of eugenics as a world movement and as a factor in the future of human welfare.

THE RATE OF LIVING.

By RAYMOND PEARL, Ph.D., Johns Hopkins University. London: University of London Press, Ltd. 1928. Pp. 185. 10*s.* 6*d.*

ACCURATE knowledge of the biology of groups, as distinct from the biology of individual organisms, has until recently been almost wholly lacking for any animal except man. A group of living things considered as a group has attributes and qualities peculiar to itself, and on the description and measurement of these attributes rests the foundation of the science of group biology. Prof. Raymond Pearl has devoted much attention to this new science, and in his latest book he reviews some of the main results of the experimentsl study of group mortality in the fruit fly, *Drosophila melanogaster*. In a clear introductory account of the laboratory technique employed in the collection of data, he emphasises his conviction that the lack of precise repetitive uniformity, which is commonly believed to be inherent in biological as contrasted with inorganic phenomena, is due in no small part to "general sloppiness and lack of specific, pertinent backgrounds of general knowledge in the conducting of biological experiments." Months, or even years, of careful observation of the habits of the subjects of experiment may be required before really significant experiments can be carried out.

Life tables are presented for the normal wild type fly, and these, when relative ages are compared, are very similar to those for human beings. But the life curves for the vestigial mutant of *Drosophila* are quite different. These differences are found not to be exclusively determined by environmental influences, although one particular environmental factor, density of population, is capable of converting the life curve of the normal wild type fly into that characteristic of vestigial flies at optimal densities. Further lines of inquiry were planned to probe deeper into the subject of life duration. An organism by virtue of its organisation is held to possess *inherent vitality*, which is manifested by the performance of certain vital actions in the absence of exogenous sources of matter and energy. With this conception further experiments with the following results were carried out. Wild type flies were reared under conditions of complete starvation and their life curves calculated. These (on a relative age base) are identical in form with those found for the same fly when fully fed. Thus the *form* of the life curve is the same whether the duration of life of the individuals comprising the group is an expression of total or only of inherent vitality. Under conditions of complete starvation differences in population density were found to have no effect on duration of life or on the form of the curve, which means that the profound effect of overcrowding in normally fed flies is not the result of any alteration in the inherent vitality of such flies, but merely curtails the bringing to expression of the potentialities of the inherent vitality. Since growth is a further expression of inherent vitality, supplementary proof can be sought and is afforded from investigations of this variable. Differences in the duration of life of flies and of growth rates in canteloup seedlings, under conditions such that these vital actions are the expression solely of inherent vitality, turn out to be the same in form. It would therefore seem to be demonstrated that the form of the distribution of differences of inherent vitality among different individuals is substantially the same in such widely different organisms as an insect and a plant. If rate of growth and duration of life be measured for the same organism under conditions such that only inherent vitality is expressed, a substantial negative correlation is found between these two variables. This and other evidence

supports the general conclusion that the duration of life varies inversely as the rate of energy expenditure during life. In other words, the length of life depends inversely on the rate of living.

The methods of analysis are essentially statistical, but the book is admirably written and should prove of great interest to the biologist.

JOURNALS.

ENDOKRINOLOGIE.—*Zentralblatt für das Gebiet der Inneren Sekretion und Konstitutionsforschung.* Edited by Prof. LEON ASHER and Prof. ARTHUR BIEDL. Leipzig: J. A. Barth. 1928.—This is a new monthly journal the publication of which is justified on the ground that up to the present there has been no scientific German journal dealing specifically with endocrinology. The morphological, experimental, and clinical aspects of endocrine investigation will be within its scope. The first issue consists of 80 pages, of which approximately half are devoted to five original articles and the remainder to abstracts of recent literature. The abstracts are about 150 in number and are in many cases of greater length than is usual. The five original articles in the first issues are by well-known authorities, and the journal should serve as a readily accessible source of German work on endocrinology. The first issue dated January, 1928, contains articles on Leydig Cells in the Human Testis by Prof. Alfred Kohn; Ovulation during Pregnancy brought about by Anterior Lobe Pituitary Hormones by Prof. B. Zondek and Prof. S. Aschheim; Infantile Myxœdema by Prof. F. de Quervain; the Function of the Intrarenal Tissue of the Torpedo by Prof. B. Kisch; on the Action of the Male Sex Hormone Obtained from Plants by Prof. S. Loewe.

The paper by Prof. Zondek is of exceptional interest. He brings forward evidence to show that ovulation can be made to occur in the pregnant mouse by means of implantation of the anterior lobe of the pituitary gland. After the implantation the follicles ripen, burst, and ova reach the tubes. The state of the ova varies; some show a well-developed nucleus, others a nucleus broken up into chromatin threads. In the majority, however, it is pigmented and degenerated. The ovary itself in this experiment shows in addition to the corpora lutea graviditatis young corpora lutea from the follicles produced under the new stimulus. These phenomena occur side by side with living fœtuses in the uterus. The amount of anterior pituitary implanted varied from 50 to 100 mg.

The third issue of the journal (March, 1928) contains original articles on the Hyperfunction of the Liver in Graves's Disease by Prof. N. Pende of Genoa, and on the Ovarian Hormone and Blood Calcium by Drs. M. Reiss and K. Marx. Prof. Pende discusses the connexion between the functions of the thyroid and the liver. It has been found by various observers that the livers of thyroidectomised animals show certain changes—namely, cloudy swelling, fatty infiltration and atrophy, and diminution in glycogen content. There is also an increase in blood cholesterol, diminution of, urea and an increase of amino-acids. It is known, moreover, that in hypothyroidism the blood-sugar curve is low, indicating diminished glycogenolysis. It has therefore been concluded that hypothyroidism is accompanied by hypohepatism. Prof. Pende attempts to show that the analogy can be extended further so as to correlate hyperhepatism with hyperthyroidism. The investigations which he has made include observations of the blood-sugar curve and other liver functions in patients with Graves's Disease. The results are interpreted as showing that in each of the liver functions tested the patient with Graves's disease shows an exaggeration of the normal picture. The findings are suggestive, but it remains doubtful whether the existence of a condition of hyperhepatism has been proved. Dr. Reiss and Dr. Marx discusses the relationship between the ovarian hormone and the blood calcium. Using rabbits and Biedl's preparation of ovarian extract they were able to show that the blood calcium could be lowered as a result of daily injections from a control value of between 14·1 and 15·3 mg. per cent. to 11·3 mg. per cent. The experiment seems to have been well controlled and the conclusions justified.

ROSS INSTITUTE AND HOSPITAL FOR TROPICAL DISEASES.

THE annual report for 1927 reaches us as we go to press. The resignations from the Council of Sir George Maxwell, and of Colonel Walter G. King, are recorded with regret. During the year, at the invitation of the Spanish Government, a visit was paid to Madrid by Sir Aldo Castellani, who gave lectures on malaria before the Royal Academy of Medicine and other societies. At the Seventh Congress of the Far Eastern Association of Tropical Medicine, held in Calcutta in December, 1927, the Institute was represented by Sir Malcolm Watson, who proposed two resolutions, which were seconded by Lieut.-Colonel S. R. Christophers, and passed by the Malaria Section of the Congress. In the first resolution it was suggested that plans for railways, canals, harbours, and all similar engineering works likely to affect the conditions producing malaria should be submitted to the proper public health authorities before being sanctioned by governments. The second resolution emphasised the fact that while there is no single method of malaria control applicable to all conditions and all countries, in large towns or works the control of the breeding places of the malaria-carrying species of mosquito is a method which should be employed whatever other anti-malarial measures are put into force. For wide rural areas, especially those with scanty, poverty-stricken populations, the first step in the control of malaria is adequate research, since suitable methods of prevention may vary in different districts. The need not only of thoroughly trained malarial research officers but of expert malarial engineers in any type of malarial prevention was stressed by the Congress. Sir Malcolm Watson, after many years active malaria control work in the Malay States, has now joined the Institute as Principal of Malaria Prophylaxis and Control Department.

There was a very large demand from India and the Colonies for the report on malaria control in Malay and Assam by Sir Ronald Ross, following his tour of inspection in 1926–27.

Anti-malaria Propaganda Work.—In order to obtain a general idea of the manner in which malaria was being dealt with in different parts of the Empire, the organising secretary, Major H. Lockwood Stevens, made a tour of India, the Federated Malay States, and Ceylon, and also visited Burma. His tour will be the subject of a special report.

Research Work.—Dr. P. Menon has carried out experiments on the poisonous effects of Paris green on the aquatic stage of mosquitoes other than anopheles. Work on fungi and fungal diseases has been continued. Several new species of mycetes and bacteria have been described. A satisfactory treatment for epidermophytosis of the toes (so-called mango toe) has been found. Experiments have also been carried out on the longevity of certain microbes. Dr. J. A. Shaw-Mackenzie has continued his work on the blood and tissue changes in cancer with reference to diagnosis and treatment. Independent confirmation of some of his conclusions has been obtained by Prof. W. C. Lewis and Mr. R. F. Corran working at Liverpool, and by Prof. D. Gardner, of Paris. Mr. J. Jackson Clarke has been engaged in further experimental study of diseases in which both specific alien cell-inclusions are present, and filter-passing stages of parasites have been found.

A list of scientific publications, addresses, and reports by members of the staff of the Institute, visiting medical men working at the Institute, and a statement of accounts concludes the report.

THE LANCET.

LONDON: SATURDAY, JUNE 16, 1928.

MEDICAL STATISTICS.

THE status of that branch of research concerned with statistics as applied to biological problems is now very different from what it was 30 years ago when Prof. KARL PEARSON was publishing the earlier memoirs of the series of fundamental researches which have so profoundly modified the aims and methods of statistical investigation. It is not claimed that any contribution to the science or art of clinical or preventive medicine of first-rate importance during the last 30 years has been the direct result of purely statistical investigation. But there can be no doubt that PEARSON and his school have raised the standard of medical discussion in the English-speaking world, so that many, even amongst those who believe themselves to be hostile to the teaching of the biometricians, have cause to be grateful to them for lessons in logic not wholly wasted. Two results have followed. Collective investigation, the team-work which—for other reasons than those we are discussing—has grown into fashion, is much more efficiently carried out than in the past; therapeutic claims of doubtful validity are, in spite of the immense opportunities for the exploitation of credulity which the developments of popular journalism and commercial advertisement provide, more sceptically received and, on the whole, less commonly accepted at full value than a generation ago. No doubt the cynic—particularly if he has read Prof. E. C. DODDS's illuminating article in THE LANCET of June 2nd—will retort that many medical men do still display in the employment of, say, "endocrine" therapy a too ingenuous faith in the general impressions which GALTON stigmatised as no more than superstitions. We admit that there is need to raise the standard of logical appraisement in clinical medicine still more. But the insistence of the biometricians upon statistical standards, their demands for numbers and percentages, have already done good and will do more good yet.

Wholly apart from the question as to what may be achieved by the application of the more recondite of modern statistical methods, such work as that of Dr. JANET LANE-CLAYPON [1] in establishing arithmetical standards by which the mass results of various surgical procedures may be appraised, has been of the greatest practical value. That work, which has always been submitted, before publication, to the criticism of experienced clinicians, illustrates the importance of the coöperation for which Dr. PERCY STOCKS pleads in the article and letter which we publish in our present issue (pp. 1242 and 1250). Medical practitioners can, and should, use many statistical methods for themselves, but statistical technique, like that of any other branch of science, has been so greatly extended that specialisation is inevitable, and many statistical problems—like that of cancer, to which Dr. STOCKS refers—cannot be solved without coöperation. The future of medical statistics is full of promise, and we trust that Dr. STOCKS's appeal will not be unheeded. The claims made by him on behalf of the statistical method as an instrument of medical research are not exaggerated; probably any of the few medical-statistical enthusiasts who were writing a generation ago would have claimed more; but this modesty of statement does not result from weakness or disappointment, but is both a sign and a cause of strength.

There is one aspect of the subject which demands comment. There is a general belief in our profession that statistical research, or even the perusal of the results of such research, is a hopeless undertaking for any but those who have an aptitude for, or at least considerable knowledge of, mathematics. It is foolish to cry peace where there is no peace, and we shall not deny, first, that a considerable proportion of the papers dealing with medical statistical problems are, and must be, written in a language which the ordinary medical reader cannot understand; secondly, that probably no living medical man in this country has a sufficient mathematical equipment to enable him to make any sensible contribution to the development of statistical theory which owes almost all its refinements to the labours of consummate mathematicians, the Bernoullis, the Laplaces, the Pearsons, and the Tschouprows of different ages and nations. But that statistical research work of the greatest importance has been, *and will continue to be*, effected with a technique and described in a language which any educated man can understand, was demonstrated by FARR a generation ago, and Dr. T. H. C. STEVENSON in our own time continues to give proofs of the propositions. We do not think the high price, or the traditional reputation for dullness, of blue-books is a sufficient excuse for the prevailing professional ignorance of the important researches published in the Annual Reviews and occasional Supplements of the General Register Office. If more of our readers would study these reports, they would realise how interesting and how clinically suggestive are many results which can be reached by the sagacious application of very simple statistical methods, and Dr. STOCKS—to whose undertaking we heartily wish success—would find no difficulty in obtaining the coöperation he seeks.

[1] See THE LANCET, 1926, i., 618; 1926, ii., 671.

PROFESSIONAL PROTECTION.

THE need for the practitioner to insure himself against the risks of expensive professional litigation is now more urgent than ever. Membership of one of the defence societies provides protection at the cost of an almost negligible premium (which a doctor is allowed to deduct from income for income-tax purposes); it should be regarded as an indispensable step on the part of everyone who enters the medical profession. It is not only that there is the risk in exceptional cases of vindictive verdicts with heavy damages. There is also an increasing readiness to formulate against members of the medical and dental professions complaints and criticisms to which reply must be made whatever the expense. This tendency is partly due to the general spread of education in health matters, partly to the national health insurance system which provides machinery for ventilating real or imaginary grievances against the panel practitioner without serious cost or responsibility on the part of his critics. A cheap and widely read daily press seems to give special prominence to any proceedings in which a doctor is defendant, and it is undoubtedly true that, when publicity has been given to a particular case, the incident is sure

to be followed by a crop of similar claims arising all over the country. It is thus the more desirable that every action against a practitioner in his professional capacity should be defended with the utmost vigour and the best available skill. Valuable time and money can often be saved by settling claims before they are brought into court. In this kind of work experience is all-important; the legal adviser who, for all other purposes can be relied upon, will rarely be able in this particular field to give the expert assistance which is at the disposal of the solicitors to the defence societies who are dealing with such matters every day. Complaints of careless diagnosis or negligent treatment, libel and slander actions, allegations of wrongful certification under the Lunacy Act—these and other dangers are regular risks in the practice of medicine. Those who help to operate the National Health Insurance Service, or who hold public appointments in institutions and poor-law hospitals, know themselves to be exposed to special attack. In the "Conduct of Medical Practice," published in book form by THE LANCET last year, it was pointed out that, in framing a contract for medical partnership or the engagement of an assistant, it is prudent to stipulate for membership of one of the defence associations. In partnership matters, indeed, quite apart from protection against litigation and the complaints of patients, the defence associations can give their services for the just and sensible solution of disputes between the partners where the law-courts are powerless, and where publicity is of no advantage to anyone concerned. The stronger, therefore, the membership of the defence associations, the stronger the position of the profession, both in its relations with the rest of the community and in its relations with its fellow members.

These general observations are prompted by a study of the annual record of the activities of one of the principal defence associations—the recently published report of the London and Counties Medical Protection Society, and similar sentiments have been expressed when the officers of the Medical Defence Union are giving an account of their stewardship. Membership of either body in no way absolves the member from the exercise of prudence or from maintaining the high standards of an honourable profession In such matters as the signing of certificates exactness is essential. If, for example, a doctor must give a certificate in respect of a patient whom he has not seen that day, this fact should be made clear. Further, as a matter of common sense and in their own interests, the members of a defence association should refer matters immediately to that body before dealing with them in any other way. Barristers have a favourite saying, that the man who is his own lawyer usually has a fool for a client. Not less than the medical profession, the legal profession is entitled to be called in early and to be given the fullest information. For his own protection, too, a doctor or surgeon should invariably secure X ray examination of any injuries where there is a possibility that fracture or dislocation has occurred; out of ordinary prudence he should be careful to provide himself with proof—in case it should ever be wanted—of the evidence which such examination reveals, or else of evidence that such examination was advised and refused. It may not be out of place to add here, since medical practitioners so frequently are brought into the courts as witnesses and not as plaintiffs or defendants, that the doctor who is asked to give evidence in cases other than those (such as Coroners Act proceedings), where the fee is definitely fixed, may save himself much ultimate trouble by having the amount of his remuneration ascertained and agreed in advance. Finally, to return to a matter more directly the concern of the medical defence societies, these bodies in self-protection must insist that their services cannot be given to those whose subscriptions are in arrear; the constitution and articles of the society must always be specific upon this point. To allow the benefits of such a valuable insurance to lapse for want of the punctual and regular payment of so small a premium would be a strangely false economy.

A HIGHER DIPLOMA IN MIDWIFERY AND INFANT WELFARE.

THAT the persistent high death-rate from puerperal sepsis is a matter of grave national concern was indicated by the Minister of Health in the House of Commons some weeks ago and more recently by the appointment of a Departmental Committee to advise upon the application of modern medical and surgical knowledge to maternity problems. Responsible medical opinion is also fully alive to the unsatisfactory state of matters, as is shown by the frequent discussion of causes and remedies in the medical journals. In our issue of last week we reported a discussion opened by Dr. JAMES YOUNG at the Edinburgh Obstetrical Society. Dr. YOUNG brought forward strong arguments in favour of the view that autogenous infection played but a small part in the causation of puerperal sepsis, that contagion was less important as a factor than many have believed, and that the main reason for the persistence of the high mortality-rate was trauma to the maternal passages during delivery. A hundred years ago the practice of obstetrics was largely a matter of "standing by" and allowing Nature to effect spontaneous delivery—of only interfering as a last resort, when Nature's efforts had failed. No doubt this policy was rendered necessary by the dire results following interference in pre-Listerian days, and was favoured by the comparative novelty of, and consequent unfamiliarity with, the obstetric forceps. To-day forceps are no longer a novelty. Their method of application is familiar to every senior student. His "cleverness" in midwifery practice is likely to be often measured by his readiness to use them, while the use of antiseptics now renders their employment comparatively safe. It may be that the conditions of modern busy general practice make it more difficult for the practitioner to pursue a policy of masterly inactivity than it was in the leisurely days of a century ago. It may be, as Dr. YOUNG indicated, that the obstetrician can plead that there is an increased sensitiveness to pain, or incapacity to bear it, on the part of the modern woman, as compared with her ancestors, or that her powers of resistance are less and exhaustion sets in earlier during labour. While modern technique has rendered the use of forceps comparatively safe as regards actual introduction of infection, the factor of trauma still remains, and no one who has seen many instrumental deliveries, and the bruised and lacerated tissues that seem to be the almost inevitable sequel of even the most careful and skilful use of forceps, will be disposed to quarrel with Dr. YOUNG in his contention that trauma from artificial delivery is one of the chief factors in the persistence of the high maternal mortality-rate.

If the conditions in modern practice are to blame they must be improved. Granted that forceps delivery in selected cases may actually prevent trauma, it must

also be granted that the incidence of pyrexia in cases delivered instrumentally has been found by careful observers to be larger than in those where delivery had been spontaneous. Many factors combine to incline both patient and medical adviser to hasten delivery when there is no real indication, maternal or fœtal, for interference. This is an aspect of the matter which will doubtless receive due consideration from the new Departmental Committee. It is an aspect that has been considered over and over again in these columns, while it received earnest attention from the authoritative writers who contributed to THE LANCET Special Supplement upon Difficult Labour.[1] Improvement of the conditions under which the bulk of obstetric practice is carried on, with consequent diminution of instrumental interference during the normal course of labour, will do much to diminish trauma during delivery. But this is not the only place to look for reform, and we are here chiefly concerned with the better education of the obstetrician in the practice of his art. Fortunately, in many of our medical schools greater stress is now being laid on a thorough training of the student in obstetrics than was the case a few years ago. But the difficulties are many. The curriculum is already overcrowded. The time allotted to the study of obstetrics is too short and the material available for practical teaching often scanty. Every general practitioner ought to be an obstetric specialist, with a good, practical training in antenatal work. He should know when interference is necessary, and when it is advisable to wait, and he should, when operative interference is indicated, be able to undertake it with skill and with the minimum degree of injury to mother and child. This is an ideal that is probably impossible of attainment by the undergraduate student. A certain amount of antenatal training he may get. He may learn the principles governing the conduct of labour, but experience and skill in the actual conduct of abnormal cases can only come by practice on his own account, under the supervision of those who already possess these qualities. This implies post-graduate work, and especially a term as resident in an obstetric hospital. After such a term of residence the possession of the necessary theoretical and practical knowledge might well be indicated by the granting of a higher diploma. If this were done the general level of professional training in a most important branch of our learning would be raised.

We have received from the Secretary of the Society of Apothecaries the regulations for admission to the "Mastery of Midwifery," the first examination for which is to be held in the autumn, and they show that the standard of the new diploma is to be a high one. Candidates must, after qualification, have held a resident appointment for six months in a recognised obstetric hospital. They must have attended a recognised antenatal clinic and an infant welfare centre for not less than three months each. One examination will be held, both written, clinical, and oral, in obstetrics and infant welfare and in the diseases of infancy. There will be three written papers, two of which will concern the science and practice of obstetrics and one the subject of infant welfare and the diseases of infancy. There will be a clinical examination at a hospital both in obstetrics and in the diseases of infancy, and finally there will be an oral examination in each of the two branches of the subject. Until 1932 practitioners of ten years' standing may enter for the examination provided that they can produce evidence that they have made a special study of the subjects for the Mastery. The establishment of the new diploma is an important step and one that should be favourably regarded by the profession as a whole. An impetus will thus be given to the post-graduate study of a group of subjects closely concerning the welfare of the nation, subjects upon which the public looks to the general practitioner for advice in directions of supreme importance. Further the Society of Apothecaries is right to believe that it will be an advantage to the public and to the medical profession that those who possess such special knowledge and experience in midwifery and infant welfare should have some mode of indicating that fact. But this implies the necessity that the really high standard foreshadowed in the regulations will be reached and maintained. Only in this manner can the general confidence of medical men be secured.

Annotations.

"Ne quid nimis."

ALKALIS AS THERAPEUTIC AGENTS IN GASTRIC DISEASE.

THE majority of physicians are agreed that alkaline salts are of great value in the treatment of gastric ulcer, but there is still a lack of precise knowledge as to the efficacy of the various agents commonly employed. Thus, whilst bicarbonate of soda is a time-honoured favourite in the hands of many practitioners and of the laity, there is a considerable volume of medical opinion which alleges that as an alkali it has decided disadvantages, and, at the other end of the scale, we find bismuth retaining its popularity in antacid treatment, although it has long been recognised that its alkaline power is of the slightest. Bourget [1] long ago laid down that whereas 2·3 parts of bicarbonate of soda were required to neutralise 1 part of hydrochloric acid, the same effect could be produced by 0·5 parts of magnesium oxide or 1·25 parts of ammonium magnesium phosphate. The same author is perhaps chiefly responsible for the doctrine that bicarbonate of soda, if administered in greater strength than 1 per cent., acts as a stimulus to gastric secretion in such a manner that its neutralising effect is more than counteracted. It is clearly desirable that we should know more about the value of the various therapeutic agents used in such quantities in gastric medication, and we therefore welcome the contribution by Messrs. Freezer, Gibson, and Matthews which appears in the *Guy's Hospital Reports* for April, 1928. These observers have carried out very careful laboratory experiments to determine the value of the various salts commonly used to neutralise hydrochloric acid, and they conclude that bismuth oxy-carbonate is the least effective of all, whilst tribasic magnesium phosphate appears to be the most suitable for the rapid counteraction of gastric acidity. They suggest at the same time that tribasic calcium phosphate, citrates, and calcium carbonate are almost equally effective, and finally they conclude that milk itself is probably the most important factor in the reduction of acidity owing to its buffer content which enables it to neutralise considerable quantities of acid. The results are of value in that they indicate certain useful antacid salts which are free of the risk of producing alkalosis such as has been observed in patients undergoing intensive treatment for gastric ulcer. But it is also clear that experiments carried out entirely in the laboratory must be accepted with considerable reserve before their conclusions are accepted as applicable to the human subject. In his recent text book Crohn,[2] stressing the point that the modus

[1] Bourget, L.: Krankheiten des Magens, Wiesbaden, 1906.
[2] B. B. Crohn: Affections of the Stomach, Saunders, 1927.

operandi of alkali treatment is frequently not properly understood, writes :—

The solution of an alkaline salt inserted into the fasting stomach both leaves the stomach rapidly through the pylorus and is readily reduced in its alkalinity by an outpour of acid gastric secretion. Thus, a strong solution of alkali increases gastric emptying and stimulates the stomach to secrete so as to re-establish the normal acid equilibrium. If during a fractional test-meal a dose of alkali is administered through the tube it will be noted that the acid curve is immediately neutralised and the free acidity wiped out or diminished depending upon the amount and dosage of the alkali used. The secondary phase of the reaction then ensues characterised by an acceleration of the secretion of gastric juice resulting in a subsequent rise of the acid curve equal to or above the previous altitude obtained by the test-meal.

And in a later passage he adds : " One should never try to alkalinise the whole acidity of the stomach. It is a mistake, since small doses of alkali give the necessary relief by relaxing the pylorus and relieving the intragastric tension." Whether sufficient evidence yet exists to permit of whole-hearted acceptance of the views of even so experienced an observer as Crohn is perhaps doubtful, but it is certain that before any final opinion can be formed concerning the value of these therapeutic agents observations must be made on the living subject in order to determine, not only the value of alkaline salts in neutralising a volume of hydrochloric acid in a test-tube, but which of them, if any, stimulate increased secretion by the oxyntic cells, and what effect they may have in producing pyloric relaxation and regurgitation of alkaline duodenal contents.

ALCOHOLIC POISONING.

IN the United States the number of deaths attributed to alcohol has considerably increased since Prohibition was introduced. For this anomaly there are various explanations, one of the most authoritative being that of the Statistical Division of the Metropolitan Life Insurance Company,[1] that the greater mortality is due to bad liquor rather than to heavier drinking. Dr. George Bigelow, however, of the Health Department of Massachusetts, declares [2] that the thousands of liquor samples examined annually for the police by his department show no appreciable increase in toxicity. A report by Dr. H. C. Lythgoe in the same journal states that, out of many samples of liquor supposed to have caused death, only one contained a toxic substance other than alcohol, and that was an isolated sample containing 23 per cent. of methanol. Dr. Reid Hunt who tested upon albino rats 100 suspected samples sent him by Dr. Lythgoe, found that the only poisonous substance present in any quantity was ethyl alcohol. In describing his experiments he says :—

" Solutions in which a part of the ethyl alcohol was replaced by an equal amount of methyl alcohol were tolerated in larger single doses than was ethyl alcohol alone ; thus, whereas rats died from 26 c.c. of the solution of pure ethyl alcohol, they survived doses of 31 c.c. of a solution in which 10 per cent. of the ethyl alcohol was replaced by an equal amount of methyl alcohol, and survived 34 c.c. when 20 per cent. of the ethyl alcohol was replaced by methyl alcohol. If a small part of the ethyl alcohol was replaced by methyl alcohol the preparation was less toxic in both acute and chronic experiments than were the preparations containing only ethyl alcohol ; the presence of the methyl alcohol lowered the acute effects (by diminishing the amount of ethyl alcohol, but such amounts of methyl alcohol were not sufficient to have a cumulative toxic action."

Going on to discuss the problem of alcoholic poisoning in the U.S.A., Dr. Hunt remarks that a certain number of deaths have been reported in the past from drinking methyl alcohol, but that very few have occurred recently. There is very little evidence, he says, that the deaths which so often follow consumption of illicit liquor are due to anything but ethyl alcohol. A deeply intoxicated man only requires a slight further dose to kill him, especially when the liquor is very potent. In three cases of death from " poison whisky " reported to Dr. Hunt, the liquor contained 60 to 80 per cent. of ethyl alcohol and no other poison. This is an enormous alcoholic strength.

These experiments on animals are thus held to show that ethyl is decidedly more toxic than methyl alcohol; the latter is admitted to have a certain cumulative action, but Dr. Lythgoe says that there is no evidence of its being harmful in the quantities in which it is found. He reports, further, that genuine bottled-in-bond whisky was slightly more toxic than nearly all the illicit liquor examined, and states that whisky, aged in charred oak barrels, becomes more poisonous as its age increases. Such conclusions will be regarded with astonishment in this country, where well-matured whisky has long been regarded as relatively innocuous and methyl alcohol as a dangerous drink. Pantaleoni has recently found that a mixture of equal parts of methyl and ethyl alcohols is more toxic to cats than either alcohol alone, and this may possibly account for some of the anomalous experimental results. But the truth is that though rats and cats are very well in their way, the question at issue concerns only the action of these alcohols on human beings. It is conceivable that by long centuries of use man has acquired an immunity—partial rather than complete—towards ethyl alcohol, which he has never had to cultivate for the lower homologue. Again, it may be that human beings more readily develop an immunity towards one alcohol than towards another. Cats and rats, having no previous experience of intoxication, either ancestral or personal, are entirely unprotected from its action, and though this does not explain the different effects observed on the two animals, it raises a reasonable doubt about the relevance of experiments conducted on animals whose inheritance or experience is so different from that of man. At any rate it is worth recalling evidence from other sources.

In his book on " The Action of Alcohol on Man," written during the late war, E. H. Starling says that the effects of methyl alcohol are " very deleterious, and its use as an intoxicating agent for a few weeks had led in many cases to permanent blindness, due to atrophy of the optic nerve." A study of the literature of the subject shows that about the year 1898 a number of cases of blindness, due undoubtedly to the drinking of essences, were noticed in the United States and West Indies. At first they were attributed to the ginger and other characteristic constituents of the essences, but careful observation showed that the liquids which did the harm were those in which methyl alcohol was a solvent. In 1904 Buller and Wood described 275 cases of serious poisoning by methyl alcohol (153 cases of blindness and 122 of death). Later, in Berlin, 130 men drank " brandy " containing one-third methyl alcohol and two-thirds ethyl alcohol (presumably with some water). Of these drinkers 50 or more died, 42 became blind, and some recovered. Baskerville has reported 725 cases of wood alcohol poisoning, which included 390 deaths, and 90 total and 85 partial cases of blindness. There are many other recorded cases, and it has been deduced from them that the action of methyl alcohol is, pharmacologically, quite different from that of the higher homologue. The effect of a single dose of either is much the same, but with the methyl compound both intoxication and recovery are slower. It is true that in acute fatal intoxication of *lower animals* a slightly larger dose of methyl alcohol can be tolerated, but even in these species it affects chiefly the most highly differentiated nervous structures, as is shown by the prolonged coma induced ; and it is well recognised that poisons which affect such structures powerfully become proportionally more dangerous the more highly developed the nervous system of the animal. Whereas ethyl alcohol is easily oxidised to carbon dioxide and water in the animal system, and these products are rapidly expelled, the oxidation of methyl alcohol is slow and does not always go on to its final stage, formic acid apparently being slowly formed and slowly

[1] Statistical Bulletin, March, 1927, No. 3.
[2] New England Journal of Medicine, 1928, cxcviii., 227.

expelled. An animal is said to take some days to get over a bout of methyl alcohol, and it may be noted that the early effects of this spirit are not exhilarating. Whether or not it is true that ethyl alcohol "inspires us and fires us with courage, love and joy," we have no reason to suppose that pyroligneous spirit produces anything better than dullness of mind and sight.

SPLENOMEGALY DUE TO A FUNGUS.

ATTENTION was drawn in our columns recently[1] to French work performed during the last two years which goes far to prove that certain cases of the type usually diagnosed as Banti's disease or splenic anæmia are due to the infection of the spleen by a fungus. It was pointed out that in this particular type of splenomegaly the appearances presented by the spleen are identical with those described some years ago by C. Gamna as a new condition, and named by him splenogranulomatosis siderotica. So far back as 1913, Dr. A. G. Gibson, of Oxford, had noticed the presence of mycelial threads in spleens removed from cases of Banti's disease, and in our last issue Dr. Gibson, with Dr. J. Fawcett of Guy's Hospital, describes a further case in which mycelial elements were not only demonstrated in the spleen and recovered in pure culture, but the mycelia actually produced a splenomegaly on injection into a monkey and were recovered from it by culture of the blood. It is unfortunate that the monkey went the way of so many monkeys used for experimental purposes, and anticipated the end of the investigation by developing generalised tuberculosis. Even so, however, Dr. Fawcett and Dr. Gibson consider that they have fulfilled Koch's postulates and are justified in claiming the fungus they isolated as the cause of the splenomegaly in the patient and in the monkey. It is presumably the same organism as that described by Nanta as *Aspergillus nidulans*, and by Emil-Weil and his co-workers as *Eurotium amstelodami*. Sir Aldo Castellani, to whom the fungus of the Guy's case was submitted, identified it as belonging to the genus nocardia. The diagnosis of the condition from other forms of splenomegaly forming the Banti group appears to be difficult. A noteworthy feature of the Guy's case was the presence of a leucocytosis, in contrast with the leucopenia found in typical splenic anæmia. The presence of pyrexia also appears to have some importance in the diagnosis, though apyrexial cases are described by French authors and also in a recent contribution on the condition from Roumania.[2] On macroscopic examination of the spleen, suspicion as to the existence of the condition may be aroused by the presence of minute yellowish scars, when the diagnosis may be confirmed by the demonstration of mycelial threads in these areas.

HARVEY'S BOOK IN ENGLISH.

THE tercentenary of the publication of Harvey's "De Motu Cordis" has given an occasion for the disinterment of the only contemporary English version of his immortal treatise. This translation by an unknown hand was published in 1653 and again in 1673. Since that date it has never been reprinted, its place having been taken by Dr. Robert Willis's translation, published by the Sydenham Society in 1847. The new edition of the book has been edited for the Nonsuch Press by Mr. Geoffrey Keynes, F.R.C.S., assistant surgeon at Harvey's hospital, and has been printed in Holland on hand-made paper in a limited issue of 1500 copies. It is a book of great beauty, and is further distinguished by having a copper plate illustrating the valves in the veins of the forearm, engraved after a new drawing by Stephen Gooden. Mr. Keynes claims with some justice that the contemporary translation is well worth preserving, even if in respect of precise accuracy it falls short of the "dull excellence of the Victorian text." It is more vigorous and expressive than Willis's translation, and represents more nearly what Harvey would himself have written. Mr. Keynes has collated the texts of both editions of the seventeenth century, and has done such polishing as seemed absolutely necessary. He adds at the end an editorial postscript and textural notes recording the more important emendations. Scientific treatises do not often receive the care which is commonly given to works of literary interest. In the present instance it seems to have been well worth while, for the book is acknowledged to be one of the landmarks in the history of human thought. Sentiment demands that it be available in the form in which Harvey himself saw it, scholarship that it do not fall short of the standards of modern times. We congratulate both publisher and editor on the result of their labours.

THE TREND OF MEDICAL PRACTICE.

TWO years ago the Association of American Medical Colleges set itself to discover the trend of practice in the United States, and with this object addressed a questionaire to doctors, trained at 52 different colleges, who had graduated in the years 1915 and 1920. Nearly 5000 letters were sent and about 76 per cent. of the recipients answered. The results are presented by Dr. H. G. Weiskotten,[1] and without going too closely into the statistics, which contain some sources of fallacy, it may be said that certain facts have been established. First, there has been a distinct increase in the number of medical men taking to specialist occupations; assuming that those of the 1920 class who intend to specialise do so within the next five years, the number of specialists in this class will be 9 per cent. greater than in the 1915 class. Secondly, there has evidently been an increase—though not so large—in the proportion of doctors holding salaried appointments, the number of which has doubtless risen with the spread of medical education and with administrative reforms. The first tendency is, of course, connected with the urbanisation of the United States, where, as in the older communities, the people are drifting more and more into towns. Medical men prefer to work in the large centres of population, and country practice, often involving the sole charge of a few poor and widely scattered patients, is carried on under such difficulties that the cities attract most of those who wish to make a good livelihood and have the ability to do so. Thus 40 per cent. of the graduates of 1920 had made their homes in towns with 100,000 inhabitants or over, although not much more than a quarter of the population at large is thus disposed. On the one hand, this tendency arouses alarm in those who have the care of the rural population at heart, and on the other it encourages specialisation among the practitioners who have to find a living beside many others of their kind. The same course of affairs is apparent elsewhere. In Berlin, for example, there are 14·9 doctors per 10,000 inhabitants, compared with only 7·45 in Germany as a whole,[2] and over 30 per cent. of German doctors describe themselves as specialists. In considering these figures it should be borne in mind that the term "specialist" bears a wider interpretation abroad than it does in this country. In the United States the number of men taking up the branches of "internal medicine" and surgery—many of whom would not be called specialists in England—is larger than in any other group except diseases of the eye, ear, nose and throat which are generally grouped together. The inquiry by the Association of Medical Colleges was made for the practical purpose of finding out what the students wanted to learn, and Dr. Weiskotten does not speculate on the reasons which lead them to specialise. He merely remarks that "these tendencies are undoubtedly in response to opportunities offered and demands made by society upon the medical college graduates." It is worth considering, perhaps.

[1] Bull. Assoc. Med. Coll., April, 1928.
[2] THE LANCET, April 7th, p. 731.

whether in this country good work might not be done by such a body as this Association, which could consider many questions arising concerning the present and future of medical education. A voluntary association of teachers would have much greater scope than the General Medical Council, which is limited in some directions by statutory considerations.

THE LATE SIR DAVID FERRIER.

IN recognition of Sir David Ferrier's pioneer work and scientific eminence it is the welcome idea of his friends and colleagues to perpetuate his memory in some permanent form. A letter has accordingly been sent out to members of the medical profession stating the intention of raising a fund for a Ferrier Memorial, and a committee of subscribers is being convened who will meet shortly in order to decide what form the memorial should take. The letter is signed by Sir Charles Ballance, Dr. William Bulloch, Sir James Purves-Stewart, Sir StClair Thomson, and Dr. Aldren Turner, the last named acting as treasurer. Those who reply favourably to the invitation—and we hope that this will include all those invited and many others—will be placed among the first list of subscribers, and it may be mentioned that, for the purpose of publication in the press, the names but not the amount of the subscription will be made known. We trust that many of our readers, whether or not in receipt of the circular letter, will support the movement and send their donations for the Ferrier Memorial Fund, either to Dr. Aldren Turner, 18, Harley-street, W. 1, or to the Westminster Bank, 1, Cavendish-square, London, W., when a receipt will be received from the bank.

VISCERAL SENSATIONS AND COUNTER-IRRITATION.

IN his Croonian lectures, the second of which we publish this week, Dr. Charles Bolton criticises [1] the theory of visceral sensation put forward by Dr. W. W. Payne and Dr. E. P. Poulton, who have shown [2] that œsophageal pain results from a stretching force in the viscus and have attributed it to tension exerted on "pain nerve-endings" in the walls. The pain, they pointed out, may be relieved either by peristaltic contraction, which overcomes the stretch, or by postural adaptation, which increases the capacity of the organ so that the tension is reduced. Tonus was defined as the tension of plain muscle during its diastole, and it was found that pain produced experimentally was associated with high tonus. The account of their further investigations, just published [3] is of considerable clinical importance, the more so as nearly all the numerous experiments were made on the observers themselves, whose accuracy can be depended upon.

The first part of their work is concerned with nausea, and as people disagree about the meaning of this term, they begin by defining it as a sensation felt at the back and lower part of the throat, usually unassociated with pain. It is often accompanied by —but should be distinguished from—uneasy "sinking sensation" in the pit of the stomach. Nausea was induced by swallowing rubber bags containing variable quantities of air, whose pressure was recorded on a moving drum. The sensations of the subject, as signalled, were recorded on the same drum, and their relation to changes of pressure within the bag, and therefore to tension in the œsophagal wall, could thus be noted. A general transition was observed from the sensation of "nausea alone" to "painful nausea" and "pain alone." The fact that nausea was felt during œsophageal *relaxation* was held to suggest that the mechanism of its production is essentially the same as that of visceral pain, but because nausea comes on at a lower diastolic pressure than pain does a different type of end-organ is probably involved, reacting to a lower tension.

"The relation of nausea and œsophageal pain is thus very similar to the sensations of pressure and painful pressure on a skeletal muscle, or of touch and pin-prick on the skin. In each case a slight stimulus produces the specific sensation and the latter gradually disappears completely as the stimulus increases, and finally pain alone is left."

Like visceral pain, nausea can be relieved, Payne and Poulton consider, by peristaltic contraction or by change of posture; conversely it can be produced by anything which increases the tension on the specific end-organs. Dr. G. H. Oriel informs them that, at sea, the sensation of nausea is felt during the retardation of movement towards the bottom of the ship's descent, and this observation is brought into line with their own work by the statement that the retardation tends to cause "a dropping of the unsupported soft parts and, consequently, an increased degree of tension in the specific end-organs for nausea in the œsophageal wall."

The next symptom investigated was the sensation of "sinking" in the abdomen. A rubber bag was passed beyond the cardiac orifice and large quantities of air were introduced into the stomach through a catheter. The sinking sensation thus produced is regarded as due to increase of tonus in the wall of the viscus and is thus "analogous in every way to nausea." On the introduction of air a desire to eructate was felt deep in the mid-line about the level of the clavicle; the feeling was that of a lump or "globus" situated here which would be dispersed by eructation. It might also be described, they say, as a feeling of "wind," and must clearly be analogous to "globus hystericus." They regard it as "different in quantity from nausea, though the two are obviously closely related, since they are felt in approximately the same part of the body and occur during the relaxations of an œsophageal peristaltic contraction, if the tonus is slightly increased." Other gastro-œsophageal reflexes were carefully studied, including what they call the "anti-regurgitation reflex," and it was found that the effect of gastric distension on the œsophagus depends on œsophageal activity at the time of its production. The smell of ammonia stimulates this activity; it is abolished by swallowing iced water; and it is found to be greater when the subject is not paying attention to the experiment. What chiefly interested the investigators, however, was the cutaneo-œsophageal reflexes, in their relation to therapeutic counter-irritation. As usual, the activity of the œsophagus was measured by means of a bag, whilst the skin was stimulated by applying turpentine stupes, mustard-leaf plasters, or lin. camph. ammon. over the sternum or by pinching or rubbing with cotton-wool or the bare hand. The type of response was independent to the method of stimulation employed, but partly varied with the activity of the viscus just before it was applied. When the œsophagus was quiet stimulation caused immediate activity, which tended to die down after stimulation or during prolonged stimulation. When the organ was already active, counter-irritation usually decreased its activity sooner or later. The effect of rubbing or otherwise stimulating the skin at a distance—i.e., on the calf—was apparently just the same. So far, these particular experiments had been painless, but as counter-irritation is used in practice to allay pain, tests were made in which an œsophageal bag was filled almost to its full capacity, so as to produce continuous retro-sternal pain, and the result of rubbing the skin was again observed. The effect was comforting and the irritations caused a fall in diastolic pressure. According to Payne and Poulton's theory of visceral pain this relief might be traced either to a reflex increase of posture leading to a fall of diastolic pressure, and hence a lessening of tonus and tension on the pain nerve-endings, or else to frequent systolic contractions of the muscle-wall which take the strain off these endings. With an active œsophagus counter-

[1] THE LANCET, June 9th, p. 1161.
[2] Jour. Physiol., 1927, lxiii., 217.
[3] Ibid., 1928, lxv., 157.

rritation is apt to produce periodic waxing "and waning" of its movement, so that tracings resemble those of rather irregular Cheyne-Stokes breathing. As the tonus is lowered during the waning phase, while the number of contractions is increased in the waxing phase, the tendency is all the time towards the relief of pain. As, however, there was one experiment in which there was neither a fall in diastolic pressure nor an increase in contractions, the investigators admit that their theory does not provide a complete explanation. Possibly the cutaneous sensation produced by rubbing acts partly by diverting attention from œsophageal symptoms. It should be noted that when, owing to long stimulation, the posture of the œsophagus has reached its maximum counter-irritation has no reducing effect on the tonus and may even increase it.

CARLISLE INFIRMARY AND THE FEVER HOSPITAL.

AN assistant commissioner of the Charity Commission has just held an inquiry into a difficult question which has arisen at Carlisle. The Fever Hospital in that city was established in 1818 on what was then a rural site, and has ever since been managed under the terms of the original trust deed. It is now in the centre of a populous neighbourhood, which is regarded as unsuitable for an institution for the treatment of infectious diseases. Since, however, the City Corporation and the Carlisle Rural District Council have for many years past largely maintained the hospital, an application has been made to the Charity Commissioners to transfer its control from the trustees to the Corporation, and the Commissioners have prepared a scheme in that sense. This scheme is being strenuously opposed by the governing body of the Cumberland Infirmary, which is only 150 yards from the Fever Hospital, on the ground that, in the event of further extensions becoming necessary, the site and buildings of the Fever Hospital would provide the necessary means of enlargement, and that, in any case, an institution for the treatment of cases of infectious disease is in its wrong place amid a considerable population. The case for the Corporation is that to transfer the Fever Hospital to a rural site would involve an expenditure which cannot be faced. Dr. Joseph Beard, the medical officer of health, calculates that to provide a new isolation hospital with 70 beds would cost at least £5,000, without counting the site, furnishings, and fittings. The trustees of the Fever Hospital are willing to sell to the Corporation for £1000, but the Committee of Management of the Infirmary are prepared to buy it in the open market. Mr. Norman Maclaren, one of the honorary surgeons of the Infirmary, urged the importance of its extension, and pointed out that 150 beds would not be in excess of the needs of the district. Both he and the Dean of Carlisle laid stress upon the helpless position of the Infirmary if its only means of extension were removed. The position is one of great difficulty, but it would be highly regrettable if the Charity Commissioners should decide that it is better to keep an isolation hospital in a thickly peopled area than to permit a large and important voluntary hospital, with rapidly increasing responsibilities, to fail itself of its only practicable means of expansion.

DIAGNOSIS OF MEASLES BY ULTRA-VIOLET LIGHT.

Dr. W. H. Wadsworth and Dr. E. A. Misenheimer[1] decided to give ultra-violet irradiation to a child whose measles rash had faded five days before, and on exposing the skin to the rays in a darkened room they were surprised to see what seemed to be an ordinary generalised eruption covering the torso, face, and legs. This led them to try exposure to the rays during the pre-eruptive stage of measles, and they found that the eruption could be seen beneath the epidermis before it made its appearance in daylight. In 14 cases the rash showed on the skin at periods ranging from 33 to 76 hours after it became visible by ultra-violet light. The method further enabled them almost to negative a previous diagnosis of measles in two children who had been exposed to infection and whose temperature was as high as 103° F. In a case of scarlet fever the rash showed plainly 11 hours before becoming visible to the unaided eye. They express the hope that this simple procedure may be useful both as a means of early diagnosis and as a check upon tentative diagnoses in various eruptive diseases such as smallpox, enteric fever, scarlet fever, and syphilis. If their observations are confirmed there can be no doubt of their value in diagnosis. It would be a great advantage were we able to ascertain that the eruption of a given disease would appear on the skin in a certain number of hours, since it is generally held that most of the fevers are chiefly infectious in their early stages. The method might be also of value after an eruption has appeared; when, for example, the rash of rubella has broken up and imitated that of scarlet fever, which it can do closely, it would be very useful to see the original eruption by means of ultra-violet rays. Wadsworth and Misenheimer do not tell us the form of apparatus used nor do they clearly describe their technique. Probably, however, they employed a mercury-vapour lamp. In a preliminary attempt in London to reproduce their results several children whose measles rashes had been gone for three, five, and seven days, were exposed to ultra-violet light from carbon-arc lamps for ten minutes each in a darkened room, but no rash was seen. Another child was exposed 36 hours before the rash appeared, but again nothing was seen. Under a mercury-vapour lamp a child with Koplik's spots seemed to show rather more mottling than the controls, but it was thought that the pattern did not correspond with that of the rash which came out later.

[1] Jour. Amer. Med. Assoc., May 5th, p. 1443.

THE Royal Society of Tropical Medicine and Hygiene will celebrate its twenty-first anniversary by a dinner at the Café Royal, Regent-street, London, on Wednesday, June 20th, at 7.30 for 8 P.M. Prof. J. W. W. Stephens, F.R.S., the president, will take the chair, and the principal guest will be Mr. L. S. Amery, M.P., Secretary of State for the Colonies. On the following day (Thursday, June 21st), at 8.15 P.M., the annual meeting of the Society will be held at 11, Chandos-street, Cavendish-square, W., preceded by a demonstration at 7.45 P.M. At the end of the meeting Prof. E. Brumpt, of Paris, will read a paper on the Differential Diagnosis of the Intestinal Amœbæ in Man. Applications for tickets for the dinner may be addressed to the assistant secretary of the Society at 11, Chandos-street.

THE annotation on Birthday Honours, published in THE LANCET last week, should have contained the names of Mr. John Marnoch, C.V.O., Regius professor of surgery in the University of Aberdeen, who has been promoted to a knighthood in the Royal Victorian Order; Major-general Walter Holland Ogilvie, C.B., C.M.E., Director of Medical Services in India, who becomes a knight of the Order of the British Empire; and Lieut.-Colonel Henry Simpson Newland, C.B.E., D.S.O., surgeon to the Adelaide Hospital, who has been made a Knight Bachelor. The list of Appointments to the Order of the British Empire ought to have included the names of Dr. Mangaldas Vijbhucandas Mehta, of Bombay, and Dr. Kishori Lal Chaudri, Assistant-director of Public Health in the United Provinces, who are appointed Officers, and Mrs. Martha Isabel Garvice, senior lady medical officer of the Egyptian Ministry of Education, and Dr. Ruth Young, personal assistant to the Chief Medical Officer of the Women's Medical Service in India, who become Members.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. D. P. H. Pearson is placed on the Retd. List.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. W. J. Payne to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Temp. Lt. R. B. Martin relinquishes his commn.
Lt. on prob. J. G. Weston resigns his commn.
H. McNeill to be Temp. Lt.

ARMY DENTAL CORPS.

Capts. W. W. Pittuck and W. M. Ferguson to be Majs.

ARMY RESERVE OF OFFICERS.

Lt.-Col. M. P. Corkery, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY

Capt. J. K. Rennie (late R.A.M.C., T.A.) to be Capt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. G. F. Hardy, having attained the age limit, relinquishes his commn. and retains his rank.

ROYAL AIR FORCE.

Flight Lt. H. B. Troup is promoted to the rank of Squadron Leader.

Flying Officer F. F. Anslow is promoted to the rank of Flight Lt. (Dental) on promotion to the rank of Captain in the Army Dental Corps.

Flight Lt. (Hon. Squadron Leader) H. C. Perkins relinquishes his temporary commission on completion of service and is permitted to retain the honorary rank of Squadron Leader.

The undermentioned Flight Lts. (Captains Army Dental Corps) relinquish their temporary commissions on return to Army duty: F. S. S. Whiter and F. F. Anslow.

INDIAN MEDICAL SERVICE.

Lt.-Cols. J, W. D. Megaw and W. D. A. Keys (Bt. Col.) to be Cols.

Capts. J. E. Ainsley and R. A. Leembruggen to be Majs.

Lt. T. A. Malone to be Capt. (Prov.).

Lt.-Col. H. C. Keates retires.

COLONIAL MEDICAL SERVICES.

The following appointments have been made by the Secretary of State for the Colonies: Miss C. N. Twining, Lady Medical Officer (Kenya); Capt. M. Clayton-Mitchell, Resident Surgeon (Colonial Hospital, Grenada), and Dr. I. M. M. Aitken, Lady Medical Officer (Gold Coast).

"WESTMINSTER HOSPITAL WEEK."—The pathological laboratories, X ray, electrical, and other departments of Westminster Hospital were opened for public inspection on several days last week, and on Thursday there was a street collection, in addition to special collections at Waterloo and Victoria stations.

JOINT TUBERCULOSIS COUNCIL.—At a meeting of the Council held on May 19th Dr. Lissant Cox commented on a report by Dr. James Pearse (see THE LANCET, Jan. 21st, p. 154) dealing with the coördination of the public health services in county practice. In Essex, Hants, Gloucester, and East Sussex it is now the custom to appoint whole-time officers to act as assistant medical officers of health, school medical officers, maternity and child welfare officers, and tuberculosis officers. The Council considered that such a plan must be carefully safeguarded if it is not to cause deterioration in the tuberculosis service; in their view assistance in diagnosis or treatment by a consultant tuberculosis officer should be available for every case of tuberculosis, recognised or suspected. Dr. A. S. MacNalty said it was the policy of the Ministry of Health to carry out the recommendations of the Astor report. In rural areas the Ministry were sometimes asked, on the grounds of convenience and economy, to sanction the appointment of assistant tuberculosis officers who were also responsible for other public health services; in such cases the Ministry advised the appointment of a *chief* clinical tuberculosis officer with special experience, and also required the assistant officers to have had a certain amount of experience in tuberculosis.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXX.—THE AMBULATORY TREATMENT OF VARICOSE VEINS.

II.* REACTIONS, COMPLICATIONS AND RESULTS.

Normal Reactions Following Injection.

Immediate Reactions.—Apart from the actual prick of the needle as it penetrates the skin, the process should be quite painless: pain during the course of the injection means that the fluid is finding its way into the subcutaneous tissues, and is an indication for ceasing the treatment at once. After the completion of the injection the patient may experience on getting to the upright posture quite a severe shooting pain in the region of the puncture, which is invariably described as passing distally along the limb. This phenomenon is but rarely observed, and the pain never lasts more than one or two minutes.

Delayed Reactions.—The nature of these should always be explained to the patient before commencing treatment. Within about 12 hours of the injection the segment of vein becomes a little swollen and is tender to the touch; it may ache slightly, the pain usually persisting for about three days, after which it diminishes. In addition to this local aching pain some patients experience pain of more severe type on getting out of bed first thing in the morning, and sometimes on rising from the sitting to the erect position. This pain may last from seven to ten minutes and then pass off, and is apparently due to the alteration of venous pressure in the dilated veins following the change of position and affecting the vessel walls in the region of the thrombus. Some patients experience a similar pain on blowing the nose, coughing or straining, and others describe a "jumping" pain at the site of injection. This reaction of swelling and aching in the vein is always likely to be more severe where this overlies a bony surface such as the tibia, or in any situation where the bony contours do not permit the vein to sink back into the soft tissues. Occasionally slight redness of the skin over the injected segment may be seen, but this is unusual. Some patients, particularly those with a rather thick layer of subcutaneous fat, will show a slight degree of bruising along the line of the thrombosed vein. As this is always linear in distribution it appears unlikely that it is due to leakage of blood from the site of puncture. This bruising always clears up, but may take six weeks or more to do so. After about the fourth day the thrombosed vein commences gradually to decrease in size, and continues to do so for about three months. Local tenderness usually disappears within a fortnight.

General Quinine Reactions.—Constitutional effects due to the quinine in the injection are described, but rarely observed. The drug may be tasted a few minutes after the injection has been given; the patient may suffer from tinnitus or headache, or in susceptible subjects a rash may appear. Injections should never be given to women during menstruation since griping hypogastric pain may be experienced.

Abnormal Reactions.

Blood Blisters.—These are occasionally seen, and are due to leakage of blood mixed with quinine urethane into the subcutaneous tissues at the site of injection. They are usually about ½ inch in diameter and dry up in about three weeks. They can be avoided by digital pressure for a short time after the injection, followed by firm bandaging over the collodion dressing for about 24 hours.

Eschars.—These also are occasionally seen, and they are produced in the same way as the blood blisters, but the local damage is more severe, and

* Part I., dealing with General Considerations and Technique appeared last week.

they may take five or six weeks to heal. They may also be avoided by pressure and bandaging described above. Similar eschars may be developed at a point some inches remote from the site of injection, and these are mostly due to the fact that an extremely thinned and atrophic vein wall and skin is unable to react to the chemical phlebitis. Injections should never be given directly into regions where the skin is atrophic and the vein wall obviously very thin. It is a striking fact that after thrombosis has occurred these thinned and atrophic areas of skin show remarkable properties of recovery of their elasticity and suppleness.

Sodium Salicylate Method.

Of the many other solutions employed as intravenous sclerosing agents sodium salicylate appears at present to be the only one used at all extensively in this country. The solution is a sterile one of chemically pure sodium salicylate, made up in 20, 30, and 40 per cent. strengths. As the salt is not precipitated on standing there is no necessity to warm before using, but specimens should remain colourless; those showing discoloration after being kept some time should not be used, since they may give rise to untoward effects.

In essentials the technique employed is the same as that described under the quinine-urethane method, but there are certain points of detail to which attention must be paid. It is usual to commence with 2 c.cm. of the 20 per cent. solution, which should be sufficient to thrombose about 4 inches of vein. The extent of thrombosis produced by each injection must be the guide as to the strength and amount of solution injected at subsequent sittings. If the 20 per cent. solution produces the requisite amount of thrombosis, succeeding injections may be confined to this strength. If thrombosis is not produced, or if it is of very small extent, 2 or 3 c.cm. of the 30 or 40 per cent. solution should be tried until the desired result is obtained. More than 4 c.cm. of the 40 per cent. solution should never be given at one sitting. As, however, the veins appear to develop a remarkable degree of tolerance to sodium salicylate it is important to work up as rapidly as possible to the strength found necessary to produce the required thrombosis.

During the course of the injection many patients experience a cramp-like pain in the muscles of the calf, which persists for a few minutes. The local reactions following the injections are in the main similar to those described under the quinine-urethane method. My own experience leads me to believe that with the salicylate method patients get more pain immediately following the injection, but less reactionary pain. Furthermore, the extent of thrombosis is liable to much greater variations—it may be absent, and it may be excessive. But in cases which respond to this form of treatment the results are excellent.

Pulmonary Embolism.

The fear of pulmonary emboli has long deterred surgeons in this country from the employment of a method which seems at first sight to invite this disaster. That the danger of embolus is not a very real one is shown by the fact that in the cases treated by Linser (6000), Nobl (2960), and Sicard and Gaugier ("many thousands"), no single case of embolus has been observed.

In the literature of the subject I am only acquainted with four cases of death from pulmonary embolus. In some of these the technique employed was open to severe criticism, and in one case the patient had been operated on for fistula in ano. No fatality of this nature has been recorded after the use of quinine-urethane or sodium salicylate.

As a post-operative complication the risk of pulmonary embolus is about one in a thousand after a major operation, with a very much greater risk after operations on varicose veins. As a risk following injection treatment it is extremely remote, as the figures quoted above clearly show, and its interest becomes almost academic.

The reason for the absence of emboli doubtless lies in the adherent nature of the thrombi. The fact that the blood flow in varicose veins is distally directed may play some part, but this is probably only of secondary importance.

Varicose Ulcers.

The general principles to be observed in dealing with varicose veins complicated by ulcers do not differ from those outlined above. Large varices are invariably present in the region of ulcers, and are much more easily palpated than seen. Especial attention must be directed to these, but small doses should always be employed on account of the lowered tissue vitality. Once a week the ulcer and its surroundings should be cleaned with ether and all debris removed. The ulcer may then be dressed with Unna's paste or with gauze soaked in the following lotion: prepared calamine and oxide of zinc, grs. 30 of each; dilute solution subacetate of lead and glycerine, dr. 1 of each; lime water to 1 oz. The patient is instructed to repeat this dressing on alternate days after gently cleaning the ulcer with water.

Results and Contra-indications.

Cure should be attained in every uncomplicated case. Three months after the injections are complete the fibrosed veins should either be impalpable or present only as fine fibrous cords in the subcutaneous tissues. Symptoms due to the veins diminish almost from the commencement of treatment and crêpe bandages and elastic stockings should be given up as early as possible. In the ulcer cases healing is a gradual but steady process. The time taken for this to occur will depend upon the size of the ulcer and the extent of the varices. Complete healing should occur in 80 per cent. of the cases either before or soon after thrombosis is complete. In the remaining 20 per cent. of cases this process is delayed either on account of underlying bone infection or the presence of some other serious constitutional disease. Clinically it will be observed that the intolerable pain which ulcer cases suffer is lessened, or entirely absent after the first few injections.

The quinine-urethane method should never be used during pregnancy, though possibly some other sclerosing agent could be employed. The following conditions are contra-indications to all forms of injection treatment, and with the exception of the first are contra-indications to any surgical procedure. (1) Recent phlebitis in the saphenous vein area; (2) old deep thrombosis with compensatory dilatation of superficial veins; and (3) cardiovascular renal diseases.

It is undesirable to begin any injection treatment without having made a general examination of the patient, and it is advisable to become master of the practical details of one recognised injection method before trying others. The methods which have proved successful in my hands have been set out here.

REGINALD T. PAYNE, M.B., B.S., F.R.C.S. Eng.,
Chief Assistant to a Surgical Unit, St. Bartholomew's Hosp.; Registrar, Royal National Orthopædic Hosp.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL.—At the annual meeting of the Ladies' Association of this hospital, it was pointed out that while the death-rate of women patients among the booked cases is only 2 per 1000, among the emergency cases it is 50 per 1000. The former class consists of women who attend the ante-natal clinic, while the latter are cases sent in at the last minute.

BATTERSEA GENERAL HOSPITAL.—The Duchess of Hamilton has formally reopened, after renovation, the main section of this institution, which is also known as "The Anti-Vivisection Hospital." The chairman, Mr. S. C. Turner, stated that the equipment was worn out, the sanitary arrangements in a bad state, and the kitchen service inadequate, and that a new wing of 50 beds is needed. Lst year there were 18,761 casualty attendances and over 2000 cancer attendances.

Special Articles.

ON THE VALUE OF THE STATISTICAL METHOD IN PRACTICAL MEDICINE.

By PERCY STOCKS, M.D., D.P.H. Camb.,
READER IN MEDICAL STATISTICS, UNIVERSITY OF LONDON.

"General impressions are never to be trusted. Unfortunately when they are of long standing they become fixed rules of life and assume a prescriptive right not to be questioned. Consequently those who are not accustomed to original inquiry entertain a hatred and a horror of statistics. They cannot endure the idea of submitting their sacred impressions to cold-blooded verification. But it is the triumph of scientific men to rise superior to such superstitions, to desire tests by which the value of beliefs may be ascertained, and to feel sufficiently masters of themselves to discard contemptuously whatever may be found untrue." —Francis Galton.

We should all be ready to admit that without the aid of mathematics the sciences of physics, astronomy, and even chemistry would be mere accumulations of recorded observations without the possibility of linking these together into an ordered whole; in fact, they would be mere ghosts of sciences emerging from the obscurity of ignorance with no tangible shape or body. But all sciences begin by the collection and recording of observations, and it is very questionable whether any such collection of facts or experiences can attain to the dignity of being termed a science without the continual submission of the laws and theories which they suggest to the cold-blooded process of statistical verification which Galton speaks of.

It is customary to group the sciences into the "exact" sciences and those which are "descriptive," but this distinction can only be a matter of degree and not of kind. The degree of exactness of a science, when we come to think about it, is really a measure of its evolution—that is to say, of the amount of success with which the so-called "Laws of Nature" which make sense out of the happenings of the Universe have been crystallised out as definite and recognisable structures from the liquid mixture we started with. When every constituent in that solution has been isolated and its relation to every other worked out, so that the behaviour of those portions of the Universe we are studying can be predicted with a considerable degree of accuracy under every possible set of circumstances, then and not until then will the evolution of the science which deals with phenomena of that kind be complete or "exact" in the real sense of the term.

No science has yet reached that point, but some have advanced farther on the road to it than others—that is to say, the relations between some of the constituents of the solution are now defined and understood sufficiently to make it possible to predict behaviour in certain circumstances with some confidence. It is *the success of this prediction which is the acid test of the exactness of a science.* There is no a priori reason to suppose that the science of physiology, for example, is essentially any less exact than that of astronomy; the only reason why it seems so is surely because it is so much easier in astronomy to isolate the different units and the different factors acting upon them than in physiology, where we have greater difficulty in disentangling all the multiplicity of influences at work at one and the same time. Not until every one of the factors acting and reacting on each organ of the body has been studied so completely that the behaviour of that organ can be accurately predicted under a given arrangement of these factors can physiology be said to have attained to "exactness."

And here let me remark that we cannot be sure that in this sense any science can ever be perfectly exact, for we have no certain proof that the same set of causes necessarily results always in the same effect; all we know is that in certain kinds of reactions, particularly in physics and chemistry, a very close prediction of the result can be reached by fixing all the known factors. An absolutely accurate agreement with prediction is scarcely ever secured even here—that is, the results of an experiment repeated under the same conditions always show some degree of scatter about a mean value. Though we naturally attribute all such variability of the result from the prediction as due to our not knowing or taking into account all the variables, there is no proof that we could ever obtain perfect accuracy in prediction even if all the variables were known and fixed.

This takes us dangerously near to metaphysics, and we may content ourselves with the statement that at any rate, whatever the ultimate limits are, the exactness of a science increases as we are able to isolate *and measure* the action and reaction of all the various factors concerned in the phenomena with which the science deals. If we admit the crucial test of our ability to predict happenings with given arrangements of causes, then we must admit that without measurements of a multiplicity of factors concerned, most sciences can never be adequately developed, and this is where the study of statistical methods comes to our aid, for statistical methods have been defined as "methods specially adapted to the elucidation of quantitative data affected to a marked extent by a multiplicity of causes."

Statistics and Medical Practice.

How does all this concern the general practitioner? It concerns him vitally, for his whole aim is to so understand all the forces at work in the human body that, starting from any given derangement of the cells or functions in that body, he will ultimately be able, by modifying or helping or checking this force and that force, to arrive at the required result—namely, the perfect health of the body—nay more, to prevent it ever being departed from.

But, it will be said, we are a long way from that and it is rather in the clouds. Let us come to earth then and notice that both diagnosis and treatment as we have to practise it to-day and to-morrow rests on the law of probability, which forms the basis of a great deal of what we know as the theory of statistics. When we started to practise we found to our dismay that not many diseases conformed even approximately to any type described in a text-book, and the process of diagnosis usually consisted in weighing, one against the other, the probabilities that various signs and symptoms arose from certain causes. We may not be conscious of it, but the fact remains that these probabilities are, in the process of our decision, being estimated on the basis of our previous experience or from what we know about the accumulated experience of our predecessors. Thus, assuming that we are making the utmost use of all the knowledge that has been gained, the accuracy of the diagnosis depends upon (1) the amount of previous experience which has been collected together by ourselves and others; (2) the manner in which it has been analysed, defined, and measured, so that any combination of symptoms can be equated to a definite probability of a set of "causes."

Again, when it comes to treatment we are not in the happy position of the physicist who can stake his life on the "certainty" that when he heats a gas it will expand, or of the chemist who can be sure that when he adds a mineral acid to blue litmus it will turn red. What we have to do, since our science is not so precise, is to weigh up the probability that a certain line of treatment will benefit the patient, and this probability is entirely based upon past experience of that treatment in the presence of similar symptoms, and is the more likely to lead to success in proportion to the care and accuracy with which the past experience of it has been analysed. To put the matter in another way, in the practice of medicine we can rarely, if ever, so standardise all the variable factors—even if we knew all about them the human element would usually compel a compromise somewhere—as to be able to promise without

reservation that a certain result will follow a certain plan of action. All we can predict is that if such and such a plan be followed there will be a *tendency* for the desired result to follow. In other words, instead of causation we have to do with *correlation*—that is, however carefully we may fix the conditions there will always be some variability in the result which we cannot control.

It is with the study of this variability and its effect on the precision with which we can predict results in the presence of a multiplicity of factors, of which only a few can be controlled, that a very large part of statistical theory is concerned, and I therefore contend that its importance for the advancement of medicine from empiricism to exactness can scarcely be exaggerated.

Dangers of Hasty Generalisation.

I do not need to quote examples to show how often in the past, over long periods of years, tens of thousands of patients have been subjected to some form of treatment in the erroneous belief that it had been proved to be beneficial, whereas an application of statistical methods at an early stage might have shown that it was useless. It is by this kind of thing that the progress of medicine has been so often retarded and much expensive effort wasted; some medical practitioners attribute the cure of a malady to a particular treatment because they have seen it associated with that event in a few cases; others attribute it to another treatment for the same reason, whereas both are mistaken in having hastened to generalise whilst overlooking the normal expectation of coincidences, which could easily be measured by the theory of probability. Most diseases have been attributed to chills and syphilis on this account.

Quetèlet, the great Belgian statistician, in one of his fascinating Letters on the "Theory of Probability," published in 1846, makes some caustic observations about medical men; thus he writes:—

"The doctors will excuse me if I retort upon them a little of the scepticism which they generally use pretty freely against statistics. If I suppose that they treat at hazard and without doing good or ill, it will follow from the law of possibility that the greater number will lose but few patients. Some will lose many and keep silence; others will save many, and it is generally these who will raise their voices. In stating the results of their practice, and I think them sincere, they only establish a fact which I willingly accept. Where is the evil? It is found in their sudden abandoning statistics to throw themselves into the domain of conjecture. They do not confine themselves to stating 'I have saved many that were ill,' but they add 'It is because I discovered the cause of the malady that I have learnt how to apply the true remedy.' But they do not in any way prove the connexion between the effect and the pretended cause; this, however, is what they should do."

I am afraid we must admit that his words are not quite devoid of sting to-day. At any rate it is still possible for the editor of a leading newspaper to write of us (May 26th, 1928)—let us hope it is mostly in jest:—

"All I can say is that the faith of doctors in doctors arouses my stupefied admiration. Their gift of superstitious credulity makes me gasp with envious reverence. If I could believe in all they believe in I could believe in anything."

Statistics and Public Health.

The general principles I have endeavoured to outline apply still more emphatically to the domains of public health, where the care of the individual gives place to the care of a population. We are now so accustomed to think of birth-rates and death-rates as definite entities that it comes as a shock to realise that the idea of the stability of statistical ratios is a relatively modern conception; in fact, it may be said to have originated with John Graunt, who published in 1665 his "Observations on the Bills of Mortality," a work of great historical interest to all students of vital statistics. By his study of the records of burials and christenings in London, Graunt succeeded in demonstrating some of the most important facts in vital statistics, which were quite unknown—viz., the regularity, when studied in mass, of vital phenomena such as accidents, deaths, and other social events, the relatively high mortality-rate in infancy, the greater mortality in towns than rural areas, the excess of male over female births, and the roughly equal numbers of the sexes in the population.

Once it was realised that births and deaths followed definite laws of probability in the mass, the way was open to all kinds of advances in social science; for example, the evolution of the principle of life insurance quickly followed, with the foundation of some of the great assurance companies. Along other lines Graunt's work was followed up by a succession of workers down to Dr. Farr, who built up our national system of vital statistics. It has been truly said that there could not have been a Public Health Act without vital statistics, and that almost every useful advance which has been achieved since in the direction of improving the health and well being of the nation has resulted from the collection of statistical data, scientific treatment of them, and a correct interpretation of their significance.

Value of Accurate Death Certification.

It is therefore surprising how slight an interest the average medical man in practice takes in such work, for the foundations of our national mortality statistics, which have been a pattern to the world, were laid by Dr. Farr without the aid of any Public Health departments and almost entirely upon the information regarding deaths furnished by medical practitioners throughout the country, and it is still true that through the medium of the certification of deaths and notification of infectious diseases the general practitioner is responsible for almost all we can learn regarding the principles which underly the rise and fall of epidemics and the incidence of other important diseases such as cancer.

It is not necessary to stress the fact that the value of any such system of national vital statistics, and of the conclusions which can be drawn from them, depends ultimately on the amount of care which each individual medical man devotes to making as accurate a return on the death or notification certificate as it lies in his power to do, for although it may be true that certain kinds of chance errors tend to cancel out in the aggregation of large numbers, it is also true that the massing together of careless observations could scarcely lead us anywhere. This is especially true in regard to cancer at the present moment, for the statistical method is as likely to unearth a clue to its causation as any method which is being employed; hence the importance of endeavouring to secure the utmost possible accuracy in death certification of this disease, and to this all such considerations as the private prejudices of relatives of the deceased should give place. It should surely give us serious cause for thought that the Registrar-General should have to form the conclusion that the very large local variations in registered cancer mortality in England and Wales which remain after allowing for all other known factors may be attributable to differing accuracy or faithfulness with which medical men in different districts enter cancer as a cause of death on death certificates, a view with which I personally do not agree though I admit there is much to support it. That it is at least of some importance cannot be doubted. Here then is a great service which the medical man can render to the advancement of knowledge in the ordinary course of his practice.

Team-work in Cancer Research.

But there is another form of service which he can render, one which must mean a little sacrifice of time and energy without compensation other than the satisfaction of having tried to make his unique opportunities of observation useful to those of his colleagues who, like himself, are honestly trying to establish the causes of disease and the best means of treatment, but by methods with which he may be frankly bored. I refer to the voluntary participation in such inquiries as that on the treatment of varicose

ulceration now being carried out by the British Medical Association. It must necessarily be that some inquiries of this kind, however carefully planned, may lead to nothing after entailing much labour to a lot of people, but that is true of all research work, which has to record many failures to each success. And it is also true that we have a natural prejudice against the filling in of any more forms than the law compels us to do. Nevertheless there are great possibilities in such team work, and I make no apology for the appeal which appears in the correspondence columns of to-day's issue for offers of help in furnishing certain information regarding cancer cases. Statistical research of this kind will doubtless offer few attractions to those who find their complete satisfaction in the immediate results of a surgical operation, but to those who look ahead to a time when preventive medicine will have rendered most surgical operations unnecessary, I hope that in this brief article I may have conveyed the impression that there are some glimmerings of sense in it, and that it is quite capable of suggesting new lines of progress or even of leading directly to actual new discovery.

CHRONIC ARTHRITIS IN ADULTS.

DIAGNOSIS AND TREATMENT.

THE following is a summary of certain sections of Dr. Alison Glover's report [1] to the Ministry of Health. It records some of his conclusions on matters of everyday importance, and is intended also to draw attention to the valuable source of information which he has placed at the disposal of practitioners and public authorities.

Diagnosis.

When a patient presents himself with any symptom or sign suggestive of chronic arthritis the practitioner has two clear and urgent duties; the first the attempt to distinguish the variety of arthritis and the stage to which it has progressed; and the second, even more important, to begin that determined search for an infective focus in which later he may have to invoke the specialist's aid. It may be impossible to distinguish the variety or type of arthritis, but an attempt to do so should result in a complete record of the case as first seen—a record not confined to the joints, but envisaging the general condition of the patient as well. A scientific classification of the many forms of chronic arthritis is not yet possible, but various forms may usefully be distinguished (see table).

A certain proportion of cases will not fall into any of the groups indicated by this table, and it does not, of course, include those relatively uncommon specific forms of chronic arthritis in which the causal agent is more or less known—e.g., those following scarlet fever, dysentery, undulant fever, meningococcal infection, gonorrhœa, tuberculosis, hæmophilia, and syphilis, or the neuropathic (Charcot's) form of the disease.

Focal Sepsis.

Even in gout, the most undoubtedly metabolic disease of the group, an infective focus may play an important part in precipitating attacks, and it should always be looked for. The seat of infection may be the genito-urinary tract, appendix, bladder, intestinal tract, nasal sinuses, middle ear, tonsils, or lastly and most often, the teeth or gums. In the great majority of cases in which focal infections are regarded as causing chronic arthritis the infecting agent is thought to be a streptococcus, usually of the *viridans* group. Many other organisms, however, can give rise to the condition.

In some of the severest cases of rheumatoid arthritis, especially in young women, no focus can be found after the most careful search; moreover, infection is probably present in the mouths of 75 per cent. of the population over 40 who remain free from arthritic symptoms. Nevertheless the theory of focal sepsis has brought fresh hopes into the outlook upon chronic arthritis, and rightly considered, early acted upon, and soberly applied, it greatly improves the prognosis of at least half the cases.

Dental sepsis is of two kinds: (*a*) "open," in which the organisms and their toxins can escape into the mouth; and (*b*) "closed," in which it can escape only into the surrounding bone, the blood, or the lymphatics. Often both types are present together, and opinions differ as to which plays the greatest part. In open sepsis the area of absorption may be extensive and the dose of toxins large; secondary infection of the naso-pharynx and intestinal tract may follow. Caries by itself scarcely seems important from the point of view of arthritis, and it is the various conditions covered by the term "pyorrhœa" which are the chief open types of dental sepsis which cause arthritis.

Pyorrhœa is generally taken to mean a form of chronic periodontal disease characterised by discharge of pus around the teeth. The chief signs are gingivitis of the interdental papillæ, pockets between the teeth and gums—especially between the teeth—absorption of bone, recession of gums, deposition of hard tartar beneath the gum margins, discharge of pus from the pockets and loosening of the teeth. Many mouths show gingivitis with deposition of soft tartar on the lower front teeth and upper molars, but no pockets. These cases are rare in true periodontal disease, but are mainly due to dirt and neglect, and improve rapidly with treatment.

Closed sepsis, due to the death of pulps and the decomposition of the organic contents in the root canals, with escape of organisms and toxins at the root apex is, from the point of view of arthritis, even more serious. Often it can be detected only by radiography, for it may be associated with clean gums and perfectly healthy looking teeth. Crowned teeth are especially liable to apical infection.

Whilst the search for a septic focus should be very thorough the dental treatment adopted should as a rule be cautious and gradual, only thoroughly incriminated teeth being removed at first. Wholesale extraction is seldom necessary and can only be justified by exceptional circumstances. In view of the immense number of persons who have much dental sepsis of all kinds and yet escape arthritis it is clear that the normal human body has to have a high resistance to the organisms and their toxins.

Tonsillar sepsis, of supreme importance in acute rheumatism, comes only second to dental sepsis in relation to chronic arthritis. The septic tonsil responsible is often small and comparatively innocent in appearance. It is sometimes retracted, and the lower pole is commonly the more infected. When such tonsils are found in a patient with chronic arthritis their enucleation is essential, nothing short of this operation being worth while.

Nasal sinusitis may be secondary to dental infection. It sometimes gives rise to no local symptoms, being only demonstrable by transillumination, by radiological methods, or by puncture, the last giving the most conclusive evidence. The slighter latent forms of sinusitis are apparently more likely to give rise to arthritis than the severer forms. Willcox points out that although adequate surgical treatment is essential, it is well to proceed cautiously, and a sufficient interval should elapse before operation on other foci which may be coexistent, if excessive autoinfection is to be avoided.

Intestinal infection is usually secondary to oral or dental sepsis, often being associated in rheumatoid arthritis with achlorhydria. The colon is especially implicated, though the signs of any active colitis are generally absent in chronic arthritis, other than the dysenteric variety. Treatment should aim especially at the correction of stasis, and the Plombières douche or colon lavage is now considered one of the most efficient means of treatment. It is not, however, free from risk and should be given under continuous expert supervision, each case being considered

[1] Ministry of Health. Reports on Public Health and Medical Subjects, No. 52. Chronic Arthritis, with special reference to the Provision of Treatment. By J. Alison Glover, M.D. H.M. Stationery Office. Pp. 103. 1*s*. 6*d*. (See THE LANCET, May 12th, p. 974.)

separately. Some authorities still mainly use intestinal disinfectants administered by mouth.

The *genito-urinary tract* is a common focus of infection, and chronic arthritis is sometimes due to secondary invaders such as streptococci which have followed upon gonococcal infection. Inflammation in the posterior urethra or prostate, vesiculitis, and endocervicitis may also be important.

Respiratory infection appears to be a source of infection in some cases, whilst *cutaneous infections* may also be responsible.

Vaccines.

Vaccine therapy will be unjustly discredited if vaccines are administered while the patient still has in his body a removable focus, not removed, or one that is capable of drainage, undrained. It will also be discredited if employed too late in the disease—i.e., when the joints are fixed and deformed. In the early stages of chronic arthritis, particularly of the rheumatoid type, the skilful use of autogenous vaccine of *Streptococcus viridans*, grown, say, from the granuloma at the root of an infected molar, may be of great therapeutic value. It is essential, however, especially in the frail subjects of rheumatoid arthritis, to start with very small doses and very gradually increase them, avoiding either general reactions or signs of reaction. As many as 15 or 20 doses may be required, the intervals being at first five days, and later up to ten days. The vaccine should never be administered until the reaction from the previous dose has entirely subsided, and if a reaction with pyrexia and general malaise occur the interval should be increased and the subsequent dose halved. Too long an interval is far better than one too short.

Various forms of stock vaccine may be employed when no infective focus has been found. Injection (intravenous, intramuscular, or subcutaneous) of such substances as typhoid vaccine, proteases, sera, colloidal metals, and milk may be employed to produce a non-specific reaction with leucocytosis, high temperature, rigors, and shock. This treatment has met with considerable success, especially in rheumatoid arthritis in which no very definite focus of infection could be detected. The value of the treatment varies inversely with the duration of the disease and other less easily measured factors of resistance and hidden sepsis. Relapse is not uncommon, and some writers reserve the method for patients whose general condition is good.

Diet and Drugs.

Diet is a very important part of the treatment of chronic arthritis. Under-nourished patients with atrophic rheumatoid arthritis of the Poncet type should take a full and generous diet, rich in animal fat, and similar to that used in tuberculosis. The correction of their hypochlorhydria is desirable to this end. On the other hand, for over-weight patients with menopausal arthritis, stout patients with osteo-arthritis or gout, and indeed for most osteo-arthritics, a reducing diet (low caloric feeding) is indicated.

DIFFERENTIAL DIAGNOSIS OF ARTHRITIS.

—	Rheumatoid arthritis.	Osteo-arthritis.	Climacteric arthritis.	Gout.
Usual mode of onset	Sometimes acute; often with a febrile attack of some length.	Insidious afebrile.	Insidious afebrile.	Acute febrile.
Usual age of onset	25–40.	40–55.	45–55.	35–50.
Sex incidence	At least three times as common in females.	Approximately equal.	Females.	30 to 50 times as common in males.
Bilateral symmetry	Usually more or less bilaterally symmetrical.	Often asymmetrical.	Usually both sides.	Usually asymmetrical.
Initial changes	At first periarticular, accompanied by much fibrositis.	Chiefly endarticular at first.	At first confined to synovial membrane.	At first confined to articular cartilages.
Movement	Early considerable limitation.	Apart from sudden "locking" little interference with movement.	Not marked at first.	Little limitation after recovery from acute attack in early stage.
Wasting of limbs	Early and marked.	Only in late stages, then little.	Only in late stages.	Only in late stages.
Joints first affected	Smaller joints first affected; usually first and second phalangeal.	Larger joints affected first; most frequently commences in one knee.	Almost always the knees are affected first.	Almost always metatarso-phalangeal articulation; great toe affected first.
Appearance of swelling of joints	Fusiform.	Gnarled irregular.	Fusiform.	Irregular.
Ankylosis	Fibrous or bony common.	Rare.	Rare.	Rare.
"Jaw-neck" syndrome	Often present at early stage.	Absent.	Absent.	Absent.
Radiograph—				
(1) Early	(1) No bony or cartilaginous change.	(1) Slight lipping.	(1) No bony change.	
(2) Late	(2) Diminished density of bones; outline fairly regular.	(2) Hyperostosis; outline of ends irregular; osteophytes; narrowed articular cartilage; space.	(2) Osteophytes in about 25 per cent.	(2) Somewhat resembles osteo-arthritis, deposits of sodium urate seen as light spots.
Patient's general condition	Thin, pale, waxy; looks ill and toxic.	Often hale and well-nourished.	Usually overweight; loss of muscle tone; "girdle-obesity."	Florid, usually over weight, often tophi.
Blood picture	Slight anæmia; leucocytosis; relative lymphocytosis: low suspension stability.	No anæmia; marked leucocytosis; suspension stability less lowered.	Usually no anæmia.	No anæmia; moderate leucocytosis during attack; marked increase in sinking rate during the attack; normal in intervals.
Achlorhydria	Frequent.	Absent.	Absent.	Absent.
Basal metabolism	Often lowered.	Generally normal.	Often lowered.	Usually normal.
Blood uric acid	Generally normal.	Often high.	—	High.

A. G. Watson makes the useful suggestion that if dessert be served at the beginning of meals rather than the end it reduces the total intake of food.

Small doses of thyroid extract are undoubtedly often effective in menopausal arthritis, and apparently mixed glandular extracts may have some tonic effect in other forms of the disease. Intestinal antiseptics —guaiacol carbonate, guaiacum and sulphur, dimol, and colloidal iodine—are often used with advantage. Patients with rheumatoid arthritis and hypochlorhydria should be given dilute hydrochloric acid, ℥20, well diluted after food. Arsenic, iodine, and potassium iodine may be useful. Liquid paraffin combined with agar may be used to improve the action of the bowels.

Physical Treatment.

Once the focus of infection has been dealt with the object of subsequent treatment must be to stimulate the defensive mechanism of the body. Vaccines or non-specific proteins will produce hyperæmia, inflammation, and fever, and physical methods, especially heat, are capable of the same effect. To heat the actual part or joint there is the choice of diathermy, local mud and peat packs, immersion of limb in molten paraffin wax, radiant heat, hot water, hot water vapour, or hot sand. Physical therapy also includes

massage and manipulation and various forms of local treatment.

Balneotherapy.—Water may have various important reactions upon the body—mechanically by its invaluable support in exercising stiff and wasted muscles; by the stimulus of its impact, as in douches or whirlpool baths, or by an action attributable to substances which it holds in solution or suspension, salt, sulphur, CO_2. But its main therapeutic effects in chronic arthritis are those which depend upon its temperature. Hot baths, like protein shock, have a local reaction and a general reaction. The local reaction is a hyperæmia, whilst the general reaction is a rise in the temperature of the skin, an increase in the peripheral circulation, owing to enlargement of the calibre of the surface blood-vessels, and a quickening of metabolism. Many patients cannot take general baths, and are sufficiently treated by local heat and manipulation. Heat applied to a limb as in the whirlpool bath, at 45° C., very greatly increases the local circulation, and the blood capillaries may be so dilated that the venous blood becomes arterial in character. The application of cold following the application of heat (thermal contrast) is another method of stimulating reabsorption of arthritic exudates.

Balneotherapy is of great service in almost all forms of chronic arthritis for the following purposes:—

1. For stimulating the immunising mechanism and for aiding the absorption of inflammatory products—action resembling to some extent that of protein shock.
2. For the restoration of the cutaneous reaction, and for promoting elimination through the skin (diaphoresis), and in through the kidneys (diuresis).
3. For the relief of pain.
4. For aiding (by the relief of muscular spasm and by obviating gravity) the re-education of function in joints and muscles stiffened or deformed by previous inflammation.

The second of these functions—the restoration of cutaneous reaction—is of great importance.

A healthy skin has many functions besides its protective action. By the ingenious mechanism of its capillary circulation (in which it is said one-third of the blood can be accommodated when fully dilated) it is the principal organ for regulating temperature, and for the conservation or loss of heat; it is an important agent in elimination of waste and toxic substances, and, in addition, recent work has made it appear in the new light of a great gland with an internal as well as an external secretion. The skin has a hard time in civilised life, and in patients with rheumatoid arthritis obvious signs of defective skin action are seen; beauty is lost, the skin is pale, sallow (or even pigmented) and unattractive, the mechanism of heat regulation seems jammed on the "off" side (to borrow a railway carriage metaphor), the surface temperature is low, the skin feels cold, and unnatural sweat comes from palms and soles. The patient has lost the glow of health and feels miserably cold with the shiveriness of toxæmia. Balneotherapy attempts to encourage and re-educate the patient's skin back to the "full flush" of health.

Balneotherapy is rather an art than a science, and it is almost impossible to give precise indications for its use. In general, however, baths and other forms of physical treatment are contra-indicated in the active febrile stages of any arthritis, whilst if a patient has a removable focus of infection it is bad practice to commence balneotherapy or physical treatment before that focus be removed, save only perhaps for the relief of pain, and in certain somewhat rare cases where it is judged that the patient's resistance has been so lowered that physical treatment should come first, with a view to increasing the resistance sufficiently to allow the focus to be safely removed. Two or more forms of physical treatment administered together are more likely to do good than if they are given separately.

Diathermy is a form of heat which is of great service, and is increasingly applied both to the joints themselves and in treating foci of infection.

Facilities for Treatment.

Hydrological methods have their best hope of success when the patient can devote his whole time to the treatment in favourable surroundings—e.g., at a spa—with the advantages of change of air and regimen, and sometimes with the additional assistance to be obtained from natural mineral waters. Many forms of hydrological treatment can, however, be given with great benefit to patients using ordinary waters at hospitals other than those at the spas, and at out-patient clinics. Their employment requires special experience, a specially trained staff, and suitable equipment.

The report concludes, after references to surgical measures, with a section on the facilities for treating adult rheumatic disorders in this country, including a brief account of the spa hospitals. The need for further provision is emphasised, and recommendations are made concerning the establishment of physical treatment centres and "arthritis units." An appendix on the treatment of rheumatism by physical methods in Germany is contributed by Dr. Fortescue Fox and Dr. Margarethe Mautner.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Local Appointments.

THE medical profession in the Irish Free State is much interested in the Local Authorities (Officers and Employees) Bill introduced to the Dail last week by Mr. de Valera. The object of the Bill is to amend the Local Authorities (Officers and Employees) Act of 1926 in one particular. That Act provided that appointments under local authorities should be made on the nomination of a central board set up by the Government, the Local Appointments Board, only one nomination being made in each case. Mr. de Valera proposes that instead of naming one person to be appointed the Board should submit a panel of names from which the local authority should choose one. His argument was that the local authority should not be deprived of all power of choice in the selection of their officers. In opposing the Bill Mr. W. Cosgrave, President of the Executive Council, said that the Act had been introduced for one main purpose—to secure in the appointment the best qualified persons. Under the Bill now before the House local authorities were to be invited to ask for a panel of not less than three. This would mean that canvassing and local influence would be resurrected. The purpose of sending down more than one name could only be to invite the local authorities to appoint someone other than the best qualified candidate. He further stated that the standard of applicants for the various posts had been good. Mr. T. J. O'Connell, the leader of the Labour Party, also opposed the Bill. He said that appointments, whether made under the central government or under local authorities, and the method of making them, should be above party. He asked that there should be an inquiry into the working of the original Act, subsequent to which there might be, if necessary, agreed legislation. Mr. E. Blythe, Minister for Finance, agreed that an inquiry into the working of the Act might be extremely useful. One of the results of the present system was that there had been great numbers of candidates coming forward, which showed that they had confidence in the methods by which they could be appointed. He saw no reason why officials should be chosen by a local authority which they had to serve under, just as he saw no reason why civil servants should be chosen by a Minister, because officials were no more the servants of council or local authority than civil servants were the servants of the Minister. Dr. T. Hennessy said that before the passing of the Act it often happened that a candidate—a medical candidate—passed his final examination one day, had his degree conferred, and then went down the day afterwards and got elected to a position. Professional experience had mattered little so long as he had influential friends enough on the local board. Dr. Ward said that the corruption practised by public bodies in the

country had been put to shame by the corruption practised at headquarters. The difference was that when there was a big case of corruption in the country it was exposed, but the corruption practised at headquarters did not see the light of day. To which Mr. R. Mulcahy, Minister for Local Government and Public Health, replied that if there were details to substantiate the charge that the work of the Local Appointments Commission was tinged with corruption, those details should be given.

Medical opinion in Ireland is strongly against any weakening of the Act of 1926. In the opinion of many that Act was the greatest reform in local administration in the history of the country. It ensured that the appointment of local officials should be made by an independent body, assisted by experts, and thereby it ensured the gradual establishment of an efficient local government service. Medical men realise that appointments are now given on merit and not on grounds of family or political influence, and there is no doubt that the standard of entrants to the public medical service is improving. The only further change desired by medical opinion is one suggested in the debate by Mr. O'Reilly, an Opposition Member, —namely, the conversion of the local government service with a civil service. The medical profession has long been asking for a National Medical Service.

Royal College of Surgeons in Ireland.

The annual election of officers and council of the Royal College of Surgeons in Ireland took place last week. Mr. T. E. Gordon, who has been elected President, is professor of surgery in Trinity College and senior surgeon to the Adelaide Hospital. He served in the war at the "Dublin" (83) Hospital, with the rank of Lieut.-Colonel. Mr. R. A. Stoney, the new Vice-President, is senior surgeon to the Royal City of Dublin Hospital. He served in the war in the French army, with the rank of Médecin Majeur, and is a Chevalier of the Legion of Honour.

"FINCLURE."

"Finclure, Cent. London" is the telegraphic address of the Surgical and Medical Protection Union of London, Ltd., a body which is seeking the support of the medical profession on grounds which are set out in the following circular, placed in our hands by a correspondent:—

May, 1928.

DEAR SIR,—The attention of all Surgical and Medical Practitioners is urgently directed to the great risks which they incur by remaining outside the Union. The number of claims is greatly increasing, and it cannot be too clearly emphasised that any member of these professions who fails to enrol as a subscriber is assuming very serious risks, which no prudent person would accept. The annual subscription is £1 per annum, *and to practitioners who are transferring from another Defence Society, the subscription is* 15*s.*, and will be retained at that sum for at least three years. No entrance fee is payable on admission. The subscription includes an insurance, *unlimited in amount*, and all costs, in cases which may be raised against a Subscriber, in which he may be found liable in damages. In view of the verdicts of juries in such cases as *Harnett* v. *Bond and Adams*, it is essential that full protection should be given against any award which may be made. This Union undertakes to defend their Subscribers against all claims which may be made against them, in respect of their professional work, including liability, not only for the acts of the Subscriber himself, but of all assistants and dispensers in his employment, and of other practitioners acting on his behalf. A separate indemnity contract is delivered to each Subscriber in his own favour.

In addition to the great security which is afforded by joining the Union, various advantages are offered, the particulars of which are attached hereto.

A form of application is sent herewith.

Yours faithfully,
W. FINDLAY,
Secretary and Treasurer.

This circular letter emanates from Atlantic House, 45, Holborn Viaduct, London, E.C., and apparently from a small office on an elevated floor of the building, but there is a second address on the letter, indicating that the Union has a Scottish department located at 86, St. Vincent-street, Glasgow, where the accommodation may be more in keeping with the promises of the secretary and treasurer of the new activity. We do not know if Mr. W. Findlay is or is not the same person who has figured in the "Handbook for Recently Qualified Medical Practitioners" as secretary of the Medical and Dental Defence Union of Scotland, Ltd., 155, St. Vincent-street, Glasgow.

The following are the particulars of the advantages of joining this movement which are set out in the circular:—

1. Subscribers have an unlimited cover for damages which may be awarded, and an individual Indemnity Contract is delivered to each Subscriber when joining.

2. All cases in which the Subscriber is attacked professionally are taken up by the Union and defended, *without any discretionary power to refuse defence.*

3. Special "Surgical and Medical" Insurance Policies can be obtained through the Union for life, personal accident, motor car, sickness, and other risks. Special Insurance arrangements are offered making provision for the Widows and Children of Surgical and Medical Practitioners in the event of death. The Insurance offered is by one of the best Insurance Companies. The terms offered are exceptionally favourable, and, owing to the privileges which a Union is able to obtain, much more advantageous than can be obtained otherwise. These "Surgical and Medical" Policies can only be issued to Subscribers to this Union.

4. Subscribers are entitled to obtain legal advice on all matters relating to their professional work direct from the Solicitors and Counsel, and complete confidentiality is thus secured. Subscribers may rely on the fact that their private affairs on the matters regarding which they desire to be guided will be entirely free from the knowledge of anyone but the Solicitors and Counsel (where the latter require to be employed).

There are also set out in this communicative circular "other facilities available to subscribers," the terms for which can be obtained on application to Mr. Findlay. These include the buying and selling of practices and houses, with arrangement for financial help, the drawing up of agreements for partnerships and assistancies, the preparation of income-tax returns, the audit of professional books, and advice on investments.

Upon the advantages set out above the following comments seem fair:—

(1) An individual indemnity contract is of no use if he who offers it cannot fulfil the terms. (2) Without a discretionary power to refuse defence, Mr. Findlay will be compelled to mediate legally in cases where he will be forced to meet damages and costs in actions which should never have been undertaken—often for professional reasons. (3) The Medical Insurance Agency is already in a position to obtain favourable terms for insurance of all sorts for medical men, while paying substantial sums in support of medical charities. (4) It will be noted that solicitors other than Mr. Findlay are going to give legal advice on the conduct of medical practice with complete confidentiality; is this funny promise a suggestion that solicitors and counsel are going to give their assistance gratuitously, or what is implied by the word "entitled"?

The medical profession may wish to be guided in their decisions as to reply. The title of the new association is very reminiscent of the titles of the two well-known and substantial medical defence societies already discharging with increasing efficiency many of the responsibilities which Mr. Findlay is ready to assume. The offer to do the work of these societies and much more than their work for 15*s.* per annum instead of £1 per annum can only be worth considering if Mr. Findlay can prove the present command of large capital. No directors are mentioned and no trustees, and there is no guarantee that Mr. Findlay possesses any resources from which to meet liabilities rightly described by himself as "unlimited in amount." Thus "the great security . . . afforded by joining the Union" is obviously absent, and we cannot recommend our subscribers either to pay an annual fee of £1 in response to Mr. Findlay's invitation, or to desert either of the well-known medical defence

societies, whose guarantees and financial position are unimpeachable. Mr. Findlay's backing may be of the most substantial character, but before subscriptions are invited the nature of that backing should be disclosed.

Public Health Services.

MENTAL HOSPITAL REPORTS.

THE *Middlesbrough Borough Mental Hospital* housed 459 patients at the end of last year. The recovery-rate for 1927 was 62·2 per cent., the highest that has ever been attained. The death-rate was 8·51 per cent.; of the 40 patients who died 10 were general paralytics. Parole was granted to 50 patients, and 74 per cent. were usefully employed daily. There was rather a high incidence of severe epilepsy—12 per cent., but the tuberculosis-rate was low, 1·96 per cent., and the general health good. Time is beginning to tell on the fabric of the building, and the telephone, fire alarm, and heating system demand renewal. Two nurses obtained their certificate with distinction, and 12 more passed the preliminary examination.

The Report of *The Lawn*, Lincoln, is the last from the pen of Dr. Jean Shortt, whose retirement we recorded early in the year. There were 60 patients under care and 12 in residence on Dec. 31. During 1927 there were 6 deaths, 2 resulting from an influenza epidemic in the spring. Thirteen of the 29 patients admitted during the year came as voluntary boarders. Steady progress is being made in renovating and improving the building. Only one patient is on parole, but 16 walk or drive out attended. The report is illustrated by photographs of the grounds, and the usual statistical tables are appended.

The 114th annual report of the *Glasgow Royal Asylum* contains the abstract of a speech by Prof. J. Glaister at the annual meeting, urging increased study of psychiatry by doctors and nurses, and the Physician-Superintendent's report for 1927. There were 518 patients in the hospital at the end of the year, and over 60 per cent. of the admissions during the preceding 12 months were voluntary. This is a record of which the institution may well be proud. The death-rate was 11·2 per cent., a high figure which was accounted for by an obscure streptococcal epidemic which was reported to the Public Health Department. The operating theatre and dental room are in constant use, and a number of improvements have been effected in the structure of the building. An increase of dietary has been greatly appreciated. Occupational therapy has been considerably developed, and the Instructress presents her first report this year. Rug-making is chiefly favoured by the men patients, and sewing, knitting, and raffia by the women, but many other industries are at work. The visiting commissioner comments on the absence of noisy excitement and of destructive tendencies and depraved habits, and ascribes it to the occupational therapy department. The dentist reports that he saw 269 patients during the year and carried out 245 extractions with local anæsthesia. Very few have refused his services. The Medical Superintendent emphasises the importance of applying psychiatry to the problem of delinquency and of extending the realm of preventive psychiatry.

The *Cumberland and Westmorland Mental Hospital* housed 864 patients at the end of 1927, the number of admissions during the year being considerably below the pre-war average. Most of the patients had a very poor prognosis, reflected in the recovery-rate of 29·8 per cent. The death-rate was 6·9 per cent., and with the exception of tuberculosis and influenza there was no infectious disease. A cinematograph and refrigerating plant have been installed, and the visiting commissioners urge the remodelling of the administrative block. The dentist visits regularly. Only 13 male and 6 female nurses are certificated or registered as mental nurses. The medical superintendent reviews the progress made in the hospital during the last 30 years. The improvements in the building include a new sewage system, verandahs to each sick ward, a recreation hall, and electricity.

The report of the *Cheshire County Mental Hospital* at Parkside records an active year. There were 2394 patients in the institution on Dec. 31st, four over the normal accommodation. The overcrowding is on the male side and no solution of the difficulty has yet been found. The total number of admissions was the smallest on record since 1902, and the decrease is again among men, although the female admissions were also abnormally few. Of the 184 admissions there was no prospect of recovery in 88, so that the recovery-rate of 36·4 per cent.—a record for the hospital—is very creditable. The death-rate was also a record: 5·3 per cent., and autopsies were made on 79 per cent. of cases. The treatment of general paralysis by induced malaria continues to give satisfactory results, and a special report on it is appended. Of the 29 patients treated 7 have been discharged, 7 are dead, and 14 are undergoing remissions. Only 1 discharged patient has returned. Ultra-violet rays have proved so beneficial for mental and physical disorders that two more rooms have been equipped with mercury-vapour lamps. Radiant heat, balneotherapy, and general massage are also used. Endocrine extracts have not yielded any appreciable effects. Two cases of dysentery occurred and there was an epidemic of influenza and some pneumonia. Otherwise the general health maintained a high level. Fifty-four women and 20 men have been employed in handicrafts, and 50 more patients have been induced to take up games. A series of six monthly meetings was arranged during the winter months for medical practitioners in the area from which patients come. The programme was an attractive one, and in this activity Parkhurst sets an example that other institutions might well follow. Short reviews of work on 200 cases of puerperal insanity and on the treatment of insomnia are printed in the report, and show that the research spirit is active. The interesting conclusion of the latter investigation is that a cup of hot cocoa is more effective than nightly hypnotics. Eleven nurses and two attendants obtained their certificate during the year, and, as we have already noted, one member of the nursing staff received the M.B.E.—the first honour conferred on a purely mental-trained nurse.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 2ND, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 286 (last week 258); scarlet fever, 1585; diphtheria, 887; enteric fever, 60; pneumonia, 1182; puerperal fever, 52; puerperal pyrexia, 100; cerebro-spinal fever, 9; acute poliomyelitis, 3; acute polio-encephalitis, 3; encephalitis lethargica, 28; dysentery, 13; ophthalmia neonatorum, 98. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 26 counties: London, 5; Bedford, 1; Buckingham, 5; Chester, 1; Derby, 6; Durham, 62; Gloucester, 1; Hertford, 1; Lancaster, 15; Leicester, 1; Lincoln, parts of Holland, 7; parts of Kesteven, 1; parts of Lindsey, 2; Middlesex, 3; Norfolk, 8; Northumberland, 15; Nottingham, 9; Oxford, 1; Stafford, 31; Warwick, 2; Yorks North Riding, 6; West Riding, 59; City of York, 2; Brecknock, 3; Glamorgan, 17; Monmouth, 22.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on June 5th-6th was as follows: Small-pox, 33 under treatment, 8 under observation, scarlet fever, 1702; diphtheria, 2049; enteric fever, 31; measles, 906; whooping-cough, 153; puerperal fever, 18 (plus 18 babies); encephalitis lethargica, 69; poliomyelitis, 1; "other diseases," 25. At St. Margaret's Hospital there were 14 babies (plus 10 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns including London, there was no death from small-pox, 6 (0) from

enteric fever, 56 (24) from measles, 7 (1) from scarlet fever, 39 (6) from whooping-cough, 34 (8) from diphtheria, 38 (8) from diarrhœa and enteritis under two years, and 46 (8) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London occurred at Ealing 2, Portsmouth 1, Southampton 1, Norwich 1, and Bath 1. Of the 32 fatal cases of measles outside London, 8 were reported from Liverpool and 3 each from West Ham, Ipswich, and Birmingham. Of the 33 fatal cases of whooping-cough outside London, 5 were reported from Birmingham, and 3 each from West Ham, Liverpool, and Gateshead; while Glasgow showed 9 deaths for the same week.

The number of stillbirths registered during the week was 273 in the great towns (corresponding to a rate of 44 per thousand live births) including 48 in London.

"Audi alteram partem."

THE WAR EMERGENCY FUND.

To the Editor of THE LANCET.

SIR,—The activities of the committee of this Fund have now come to an end. The first case of distress was relieved in 1915 by the Royal Medical Benevolent Fund, but it was soon found that a special sub-committee—the War Emergency Fund Committee—had to be constituted, and that an appeal for larger funds was necessary. The War Emergency Fund was instituted to afford assistance to those members of the profession who, in consequence of having joined the medical service of the Navy or Army, found themselves in temporary financial difficulties. The late Sir Alfred Pearce-Gould, who died in 1922, was the first chairman. Amongst those who served on the committee were: Sir William Lister, Mr. F. P. Legg, Dr. Andrew Elliott, Sir D'Arcy Power, Dr. Charles Buttar, Sir William Willcox, Sir Charters Symonds (hon. treas.), and Dr. Newton Pitt (hon. sec.).

Applications for assistance were received from 297 medical men; of these 160 cases were relieved, and the other 137 cases were either ineligible or were assisted in other ways to secure the help they required. From 1920 most of the applications made were for assistance towards educational expenses. Assistance for education has been given to 75 boys and 30 girls, who have attended the following schools:—

Taunton, Bournemouth, Cranwell, Harlow, Nottingham, Tunbridge Wells, City of Oxford School, Westminster, Durham, Malvern, Wellingborough, Southbourne, Edinburgh, Bromsgrove, Purley, Hunstanton, Woolwich, Epsom, Kelly, St. Paul's, Colet Court, Tonbridge, France, Denstone, Cardinal Vaughan's School, St. Peter's York, Sunderland, Ampleforth, Malton, Wimborne, Blackheath, St. Anne's, Holt, Bedford Training College, Bury, Alderley Edge, Froebel, Little-hampton, University College, St. Bart.'s, St. Mary's, and Guy's.

Grants have also been made towards insurance, rent, maintenance, debts, surgery requisites, help towards the purchase of practices, examination fees, and the like. The total sum paid in aid of education of the children of these medical men was £18,946 9*s.* 10*d.* The total sum raised was £32,458 16*s.* 8*d.* The grants given in successive years were:—

	£	*s.*	*d.*		£	*s.*	*d.*
1917	290	4	0	1924	2,470	17	0
1918	697	16	2	1925	1,778	4	2
1919	7,552	15	2	1926	291	4	4
1920	5,926	17	6	1927	85	0	0
1921	5,622	14	5				
1922	6,204	17	9		£34,876	14	11
1923	3,956	4	5				

This letter is not written primarily to acquaint the profession of the way in which the fund has been administered, but to tell the story of the wonderful, long-continued, unobstrusive, self-sacrificing, labours of two members of the committee who investigated, visited, interviewed, and corresponded with applicants for grants. Their recommendations were almost invariably accepted by the committee, and without their aid and advice the Fund could not have functioned without making many mistakes. These facts, we think, should be known.

The whole profession will be proud to learn of the splendid selfless service to their comrades in distress rendered by Sir Charters Symonds and Dr. Newton Pitt.

We are, Sir, yours faithfully,

THOMAS BARLOW,
President of the Royal Medical Benevolent Fund.
CHARLES BALLANCE,
Chairman, War Emergency Fund Committee.

June 6th, 1928.

PROPHYLAXIS OF RICKETS.

To the Editor of THE LANCET.

SIR,—Dr. Helen Mackay's useful advice on the prophylactic treatment of rickets (THE LANCET, May 5th, p. 923) concerns only the treatment of the child, and I would like to draw attention to another way of preventing this common disease—namely, by the administration of cod-liver oil or some other anti-rachitic preparation to the pregnant woman and to the mother during lactation. The question whether this is rational has already been considered by A. F. Hess and Mildred Weinstock.[1] They administered cod-liver oil to expectant mothers in the last months before delivery and also fed pregnant rats on it and came to the following conclusion:—

"Judging from our experiments, it would seem that rickets cannot be prevented by improving the diet of the mother, (*a*) previous to pregnancy, (*b*) during pregnancy, and (*c*) throughout lactation, although it can be mitigated to a certain degree. Supplementing the diet of the mother for two generations also failed to render the young refractory. Infants were not protected by giving the mother cod-liver oil during the last two months of pregnancy. On the other hand, the fact that premature infants are markedly susceptible to rickets shows that prenatal nutrition does play a rôle. A consideration of the experimental evidence, of clinical tests, of the susceptibility of bottle-fed compared to breast-fed babies, and the striking seasonal incidence leads to the conclusion that rickets is mainly of postnatal origin. Although its incidence and severity may be influenced by improving the nutrition of the mother, our main efforts should be directed toward improving the environment and nutrition of the infant. Until these postnatal factors are corrected, we cannot hope to prevent rickets."

Little effect though Hess and Weinstock expect from the administration of cod-liver oil to women during pregnancy and lactation, yet they do not deny that, in this way, some result may be attained, and it is quite possible that the benefit would have been greater if the doses given had been larger, for here the coefficient of division (Verteilungs-coefficient) has to be taken into account, which is unfavourable for the small bodies of the fœtus and the suckling. Even less effect may perhaps be expected from the administration of cod-liver oil during lactation, it being generally accepted that mother's milk is poor in vitamin D. But may not the explanation of this be that the mother has not much of this vitamin to give? The unhygienic circumstances of life of most mothers render this supposition acceptable.

I will explain what led me to think of preventing rickets by improving the diet of the mother. For reasons of economy I had started giving the rats in our breeding-house cod-liver oil, of which we had a large supply in store, instead of butter which is more expensive. The females got 1·5 or 2 g. a week, which was a substantial dose. From the moment I took this measure all my efforts to produce rickets in their young remained fruitless, though I had never failed before. To find out the cause of this unexpected and extremely awkward result I carefully examined the material of the rickets-producing diets to find out the composition and the ratio of calcium

[1] Amer. Jour. Dis. Childr., 1924, xxvii, 1; Jour. Amer. Med. Assoc., 1924, lxxxiii., 1558.

to phosphorus, but found no deviation from the diet prescribed. None of the well-known diets (McCollum's with both hard and soft wheat, Steenbock's and Sherman's) had any effect, so nothing was left but to consider the cod-liver oil as the cause of the failure. Cod-liver oil was banned from this moment, but this measure had not immediately the desired effect, *for rats born even five months afterwards still proved refractory to rickets.* Consequently I was obliged to get rats from other breeding-pens in whose young I at once succeeded in producing rickets.[2]

I cannot put this method of preventing rickets by the administration of cod-liver oil to the test and must confine myself to suggesting it to others who can. It is true that we have effective remedies for rickets, but any one who has treated children for this disease will have found that it is sometimes long before they are cured. So here, too, prevention is better than cure. If prenatal administration of cod-liver oil should prove effective, there would be one way more, and that an easy one, to prevent the very common and by no means small evil of rickets.

I am, Sir, yours faithfully,

E. C. VAN LEERSUM.

Netherlands Institute of Nutrition, Amsterdam,

AN INQUIRY INTO THE ÆTIOLOGY OF CANCER.

To the Editor of THE LANCET.

SIR,—May I ask those of your readers who are engaged in general practice and who would be willing to answer a series of questions relating to cancer cases to send their names to this laboratory. All that is necessary at the moment is to put a visiting-card into an envelope or write name and address on a post-card and forward it to me at the Department of Applied Statistics, University College, London, W.C.1.

The object of the inquiry will be to try to throw some light on the vexed question of cancer ætiology, and this will necessitate information relating to a large number of cases from all parts of the country which cannot be obtained in any other way. The identity of the cases need not be revealed, and the forms will be so devised that scarcely any writing is required. Such appeals have sometimes met with a disappointing response in the past, and it is therefore not proposed to proceed with the investigation unless a sufficient number of helpers is first assured.

May I suggest that before deciding that the rendering of such a service is impossible or that it will only be a waste of time, the last paragraph of the article on p. 1243 of this issue of THE LANCET may be read.

I am, Sir, yours faithfully,

PERCY STOCKS,
Reader in Medical Statistics.

Galton Laboratory, University College,
London, W.C., May 28th, 1928.

"ENCEPHALOMYELITIS FOLLOWING VACCINATION."

To the Editor of THE LANCET.

SIR,—We have no desire to intervene in the discussion in your columns concerning the appropriate terminology to be applied to the pathological lesions in post-vaccinal encephalitis. But Dr. Perdrau in his reply to Prof. Turnbull and Prof. McIntosh has raised a further question which seems to us of much greater importance. He appears to take the view that acute disseminated encephalomyelitis is a pathological entity which may be associated with acute infections, such as vaccinia, or may occur without any obvious antecedent, and that pathologically the lesions in acute disseminated encephalomyelitis and post-vaccinal encephalitis are indistinguishable. We think it of interest, therefore, to record that we have, during the last two months, observed six cases of acute meningo-encephalomyelitis which differed clinically in many respects from acute epidemic encephalitis lethargica and showed a marked clinical similarity to post-vaccinal encephalitis, though none had recently been vaccinated. The ages of our patients ranged from 3 to 18 years. The onset of the illness was acute, with considerable pyrexia, drowsiness, and delirium. Cervical rigidity and Kernig's sign were present in four cases, and trismus in one. Ocular abnormalities were slight or absent. Aphasia was noted in two cases, quadriplegia in one, hemiparesis in one, and in one the principal signs were those of a myelitis. The cerebro-spinal fluid showed no gross abnormality. One patient died, one is left six weeks after the onset with total aphasia, apraxia, and weakness, and spasticity of both upper limbs, and the others have made, or are in process of making, a complete recovery. The occurrence of six cases in less than two months suggests the presence of a small epidemic. We hope to report these cases fully in a short time, when we are able to include Prof. Turnbull's report of his pathological examination on the fatal case, and Dr. S. P. Bedson's report on the results of his attempted transmission of the disease to animals. We propose in our further communication to deal with the relationship of this condition to other forms of encephalitis.

We are, Sir, yours faithfully,

DONALD HUNTER.
W. RUSSELL BRAIN.

London Hospital, E., June 8th, 1928.

MARVELLOUS MONTPELLIER MIDWIFERY.

To the Editor of THE LANCET.

SIR,—A few weeks ago I received, from a photographer's shop in Montpellier, a picture post-card containing a photograph of Prof. Delmas, of Montpellier, "ganté" but not "coiffé" (as were the midwives behind him), together with a printed notice of the professor as the author of the procedure of "extemporaneous evacuation of the uterus (delivery at a fixed hour)," and an account of this "accouchement indolore et sur rendezvous" (painless delivery by appointment).

This method consists in digital and manual dilatation of the cervix under spinal anæsthesia, the dilatation being produced, on an average, in three minutes; the child is then delivered by version or forceps, and three minutes later the placenta follows spontaneously, the whole labour being over in a quarter of an hour, "the infant in its cradle, the placenta in its dish, and the mother back in bed."

As a picture post-card is not the usual medium for the communication of medical information, I waited for the official account of Prof. Delmas's paper, which appears in the *Bull. de la Soc. d'Obs. et de Gyn. de Paris* for April, 1928. The spinal anæsthesia is produced by the injection of 10 cg. of sterile seurocain dissolved in 5 c.cm. of cerebro-spinal fluid. Amongst the 40 cases with which the paper deals, the author states "je n'ai eu que des cas heureux": one woman, however, died from acute anæmia and syncope (central placenta prævia). The child "if it had not succumbed before the extraction"—the author omits to state how many of these occurred—"was always preserved alive." The dilatation took 12 minutes in one case, 20 seconds in several cases, three minutes being the average. Prof. Delmas insists on the importance of limiting the procedure to cases where the cervix is healthy and not affected with cicatrices or new growth, and of its being carried out by specialists; and he admits that the procedure is too recent to be vulgarised—no indication of this appears in the picture post-card.

In the discussion which followed the paper there was agreement as to the rapidity with which dilatation could be carried out under spinal anæsthesia, opinions differing as to whether the latter facilitated version

[2] A more extensive report on this work was published in the Nederlandsch Tijdschrift voor Geneeskunde, 1928, lxxii., 680.

M. Forgue alluded to the risk accompanying spinal anæsthesia. M. de Rouville admitted that the operation could be done *cito et jucunde* ; but, as to *tuto*, " n'allons pas si vite et attendons." M. de Carrera had failed to turn a child after dilatating the cervix, and said he would never think of performing the operation in a normal labour, on account of the risk to the mother from the anæsthesia and intrauterine manipulations, and to the child from extraction by the feet.

Prof. Delmas's paper would have been more valuable if he had published all his cases and had stated how many children died. He gives particulars of 11 cases, of which only two were primiparæ ; in one of these the cervix could not be dilated and vaginal Cæsarean section was done ; in the other the dilation took 7 minutes, version and extraction 11 minutes. No injury was done to the soft parts, which is remarkable in a primipara of 19 whose child weighed 8¼ lb.

What of the children ? In 10 out of 11 the child was born " astonished " (étonné) and had to be revived ; one survived for 48 hours only ; the remaining child cried at once. Opinions will differ as to the cause of the child's " astonishment " ; M. de Rouville suggested that it was due to the brusque and involuntary capers it had cut in coming into the world. Personally, I was astonished, more than 40 years ago, at the frequency of visceral hæmorrhages in the child delivered by version and extraction,[1] and I cannot suppose that it was the perfection and harmlessness of Prof. Delmas's technique which caused the ten children to be " astonished," or the complete dilatation of the soft parts which caused the one child to cry out at once. Let us remember what that old Montpellier doctor François Rabelais tells us about the birth of Gargantua " in a strange manner," when an ugly old trot who had the reputation of an expert she-physician made Gargamelle so horrible a restrictive and binding medicine that the child, finding the passages obstructed below, sprang up and leaped, entered the hollow vein and issued forth at her left ear. As soon as he was born he cried, not as other babes used to do—miez, miez, miez, miez, but with a high, sturdy, and big voice, " Some drink, some drink, some drink," as inviting all the world to drink with him. " I doubt not," says Rabelais, " that you do not thoroughly believe the truth of this strange nativity. Though you believe it not, I care not much ; but an honest man, and of good judgment, believeth still what is told him, and that which he finds written."

I am, Sir, yours faithfully,

London, June 2nd, 1928. HERBERT R. SPENCER.

THE PROBLEM OF ANKYLOSTOMIASIS.

To the Editor of THE LANCET.

SIR,—In your editorial note to Colonel Clayton Lane's letter in THE LANCET of May 19th (p.1043) you commented on the advantage of possessing a summary of the problem of ankylostomiasis. Allow me, therefore, to draw your attention to a fairly recent publication edited by the Rockefeller Foundation in 1922 (Publication No. 11 of the Rockefeller Foundation International Health Board, New York City, 1922, pp. 416) and an article from the Encyclopædia, entitled Occupation and Health (No. 25) in course of publication by the International Labour Office, which in a 12-page summary gives a fairly complete account of the different aspects of this problem. You will see that on p. 11, col. 2, disinfection of mines by salt is briefly discussed.

I am, Sir, yours faithfully,

League of Nations: International Labour Office, Geneva, June 6th, 1928. L. CAROZZI.

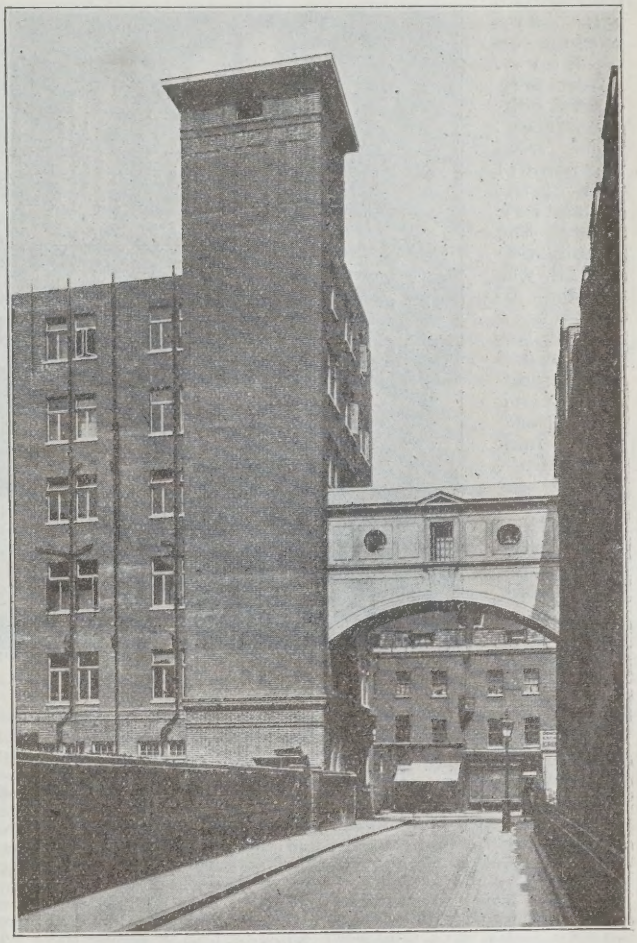
[1] Obs. Trans., 1893, xxxiii., 203.

BIRMINGHAM CRIPPLES' HOSPITAL.—The Woodlands Hospital at Northfields is about to be enlarged at a cost of £25,000. It is intended to concentrate at Woodlands all the in-patient works of the Birmingham Cripples' Hospital.

NEW BIOCHEMICAL INSTITUTE IN LONDON.

ADDITIONS TO THE MIDDLESEX HOSPITAL.

THE new building opened at the Middlesex Hospital yesterday (June 14th) really consists of two portions. The first—the basement, sub-basement, and ground-floor—is given over to hospital uses ; the sub-basement contains the central boiler house and engineering plant for the hospital and all associated buildings, the basement includes the connecting corridors and subways to the hospital, annexe and nurses' home, whilst the ground floor provides a much-needed restaurant for the students. The second portion, from the first floor upwards, is the Courtauld Institute of Biochemistry. The space available for this Institute was clearly defined by the boiler-house site. It was ascertained that it would be possible to erect a building of five storeys above the restaurant and the problem facing those responsible for the laying out of this space was a very difficult one.



The Courtauld Institute of Biochemistry, Middlesex Hospital.

A detailed tour of the principal biochemical departments of the United Kingdom, together with a careful study of the plans of some of the better-known American institutions, showed that almost all existing buildings devoted to this type of work were split up into a large number of small rooms. There are many apparent advantages in this type of construction ; it is possible to give every individual worker a room to himself and to segregate the various research problems to separate laboratories. But

experience has shown that certain disadvantages must be set against these obvious advantages. From the building point of view the number of partitions increases the complications with regard to pipe runs, &c., besides augmenting the cost very considerably. Moreover, the ventilation of a number of small rooms is usually very poor, and there can be no doubt that good ventilation is as important to the workers as is good apparatus and equipment. From the academic point of view, yet further disadvantages are apparent. A small number of separate rooms devoted to individual biochemical problems tends to divide up the whole subject into a series of water-tight compartments. By this system a man working on one problem may be deprived of the healthy scepticism and criticism of colleagues who are working on others. After very careful consideration, both from the point of view of the building and of the administration, it was decided to adopt a more or less new principle in constructing the Institute. Small rooms, except for very special purposes such as incubation and dark rooms, have been avoided, and a series of large, fully equipped laboratories have been built instead. In these big rooms a series of workers are investigating different problems, and it is hoped that with the abolition of physical partitions the mental barriers will also disappear.

Part of one of the New Laboratories.

The first floor is planned as one large laboratory for students, with a preparation room and store. The second floor contains a clinical routine laboratory with three examining rooms attached. The secretary's office is on this floor, near the staircase and lift. This floor is also connected to the Bland-Sutton Institute on the hospital site by means of a reinforced concrete bridge across the street. The third floor contains a large chemical laboratory with combustion and balance rooms, and at the end a large-scale preparation room. The fourth floor is planned to provide a library, optical dark room, standardisation laboratory, and the professor's private room and laboratory. The fifth floor allows for some extension as to half the area, the remaining portion being divided into two large animal houses, with a small incinerator room attached. Two electric push-button lifts are provided—one in the main staircase for passengers, and one for goods and food in the escape stairs. Both serve all floors.

To overcome the difficulty of providing a space in the floor for all the drainage from the benches, the constructional floor slab was placed at the bottom of the main steel beams, the space above and between the beams being used for all pipe ducts. A further advantage gained by this means of construction was flatness of ceilings everywhere. The heating is by low-pressure hot water, the pipes running round the various rooms about 2 ft. below ceiling level. Some rooms, such as the animal houses, are heated by steam. The overhead pipe system was adopted, after considerable discussion, as it was practically impossible to find suitable positions for radiators, owing to the benches and other obstacles. The laboratories are fitted up very carefully, every bench and its detailed fittings having had minute consideration. All services, such as hot water, cold water (both tank supply and high pressure), gas, steam, electric light and power, are provided wherever required.

The all-important problem of drainage from the various benches and isolated sinks was considered in great detail, and many other large laboratories were visited to see the different types in use. The methods finally adopted were governed by two important considerations: (1) The possible deterioration, through chemical action, of the material employed, and disturbance of jointing by vibration and use; (2) the necessity to prevent as far as possible any trouble from fouled waste ducts in the rooms or the building itself.

It was decided to use chemically pure lead in the form of pipes. These were laid in one piece from end to end, with all joints carefully welded. The pipes were laid to a gentle fall in shallow concrete channels, lined with asphalte, as an additional safeguard against possible leakage. These asphalte channels have an iron sleeve protruding through the external wall, to act, first, as a warning pipe, should a leakage occur, and, secondly, to form a way through which the main waste pipe goes to connect up with the main iron stack pipes. Careful arrangements are made to keep these main stacks fully ventilated and easy of access at each connexion. The horizontal lengths of pipe under the floors are reduced to a minimum. Wherever possible they are arranged under the benches themselves and well above floor level, thus making them easy of access.

The prevention of fouling is ensured by introducing laboratory traps to every isolated sink or group of sinks on each bench, thus forming an effectual barrier, and at the same time intercepting all discharges and helping to break down strong mixtures before they find their way to the lead pipe work. All soil drainage is taken separately to main external stacks.

The arrangements in the two animal houses were given special consideration. The floor is asphalte, walls distempered, and all cage racks are suspended from the ceilings. This makes the cleaning of the floors a simple matter and also helps to prevent vermin from getting to the animals. All the laboratories have white glazed brick walls, casement windows with opening fanlights, and deal floors on wood joists. Some of the smaller rooms have either a granolithic or an asphalte-finished floor. All the woodwork is stained and dull varnished. Generally, everything has been kept as simple as possible.

The new Institute will be in the charge of Dr. E. C. Dodds, Professor of Biochemistry in the University of London.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Petition against Vivisection.

On June 6th Lieut.-Commander Kenworthy presented a petition in the House of Commons, signed on behalf of 26,031 persons, praying the House of Commons to "prohibit by law the cruel practice of experiments on living animals."

Rating and Valuation Bill.

In the House of Commons on June 7th this Bill was read a second time and committed to a Committee of the whole House.

Scottish Board of Health.

On Monday, June 11th, the House of Commons went into Committee of Supply on a vote of £2,037,515 for the salaries and expenses of the Scottish Board of Health. Mr. James Hope, Chairman of Committees, was in the chair.

Slum Clearances.

Mr. Ernest Brown raised the question of slum clearances, which he said was one of the first political problems of the day. If they were going to understand the size of the problem they must decide how many people they intended to live in a room and how many families in a dwelling. The preliminary figures recently given to the Edinburgh City Council showed that there were 5000 houses in Edinburgh alone which should be marked down as unfit for human habitation. He welcomed the fact that this year 21,660 houses had been built as compared with 14,930 in 1926, and also the prophecy that next year it was hoped to exceed the 20,000 mark. With regard to slum clearance, however, they had not begun to touch the real problem in Scotland.

Mr. Stewart said that in Glasgow to-day there were 6000 people suffering from tuberculosis. Of those suffering from this disease who were living in one-apartment houses, only 57 had a room to themselves; 145 had a bed to themselves, though living in the same apartment with others; and 976 were sleeping in a bed with other people. In two-apartment houses the story was the same. There were 441 with a room to themselves and 2506 sleeping in beds with others. Out of a total of 3415, fewer than 1000 had either a bed or a room to themselves. Could one wonder that tuberculosis still persisted? To-day in Glasgow they were facing the erection of another sanatorium for 400 patients which before it was finished would have cost something approaching £500,000. To provide a separate bed for over 5000 consumptive patients would require an annual addition of 1360 houses. Surely the Government could do something to give the local health authority the power to provide sleeping accommodation for these people and to provide a separate room for a person suffering from this disease.

An Efficient Medical Service.

Mr. Macpherson said that one of the very best instruments that had ever been introduced into the medical service of any country was the Highlands and Islands Medical Service in Scotland; but the amount annually allocated for that service was only £42,000. The very special work which this service performed could not be done for £42,000 a year. He believed that about £60,000 a year was actually spent on the service. What did the Government intend to do to keep this fund solvent? The Northern Infirmary at Inverness badly needed help in order that recent appliances of science of medicine and of surgery could be procured and that the infirmary should be properly equipped and maintained. A permanent grant from the Board of Health, from the Government, or from the Highlands and Islands Medical Service Fund was urgently needed for this purpose.

Tuberculosis.—Venereal Diseases.

Dr. Drummond Shiels praised the report of the Scottish Board of Health and paid a tribute to the valuable work that had been done in connexion with it by Sir Leslie Mackenzie, who had just retired. It was a matter for regret that the progressive fall in the death-rate from tuberculosis was not maintained during the last year, but probably the reason given—the very severe climatic conditions in Scotland last year—might be part of the explanation. In Scotland many cases in an infectious stage of the disease were living in crowded homes, so that public money spent in other efforts to get rid of this disease was being wasted. He urged that continued attention with the object of securing a pure milk-supply was of great importance in combating the non-pulmonary forms of tuberculosis. He was glad that the report called attention to the very serious position in regard to tuberculosis in the Highlands and Islands of Scotland as compared with the rest of Scotland. In his view, the major causes of this contrast were (1) the very bad housing conditions in the Highlands and Islands, (2) the unsatisfactory feeding of some of the people who lived there, as they were not in a position to resist disease. He would like to have said something about the Hairmyres Colony and of that method of dealing with certain types of tuberculosis. There was no doubt that such a labour colony was on right lines. The Middle Ward District of Lanarkshire and the Board of Health were to be congratulated on coöperating in this effort to deal with tuberculosis on up-to-date lines.

The references to venereal disease in the report dealt with the general propaganda methods which were undertaken with the encouragement of the Board of Health and also with the possibility of preventive methods. They said in regard to those that certain preventive methods might be contributory to the spread of the disease. He (Dr. Shiels) thought he had heard an echo of that in other quarters. It was not the opinion of the Army and the Navy, which had reduced their figures in connexion with these diseases by the methods which were so sceptically referred to in the report. The Trevethin Committee also favoured them. He was interested to find that the Board came to the conclusion that secrecy, which was so much stressed in the debate in that House a few weeks ago, did not seem to be of great importance, at least as regards the great cities. One could see quite well that while the language used was guarded the Board of Health, as they had shown on several occasions before, were not satisfied that the present arrangements and system were satisfactory or capable of dealing adequately with these serious diseases. This certainly justified the attitude of the Edinburgh Corporation and other Scottish local authorities on the matter. It was an appalling fact that last year in Scotland the number of defaulters was 51 per cent. A very large amount of public money was spent in dealing with this subject and it was obvious that a great deal of that money was wasted, and in the name of economy, if humanity was not enough, something else should be tried.

Attacks on the Medical Profession.

Dr. Shiels commented on the return in the report to the attack made last year on the medical profession in regard to certification of people as unfit for employment. He hoped that they had heard the last of that, because in his opinion that attack, while it might have been justified in some cases, had been altogether overdone. Altogether an attitude was being taken up in regard to the medical profession, and incidentally in regard to their patients, which was quite unjustifiable. The report did not sufficiently recognise that owing to unemployment the condition of the people in Scotland during the past few years had been such that they were more liable than formerly to illness. It was unfortunate that by means of threats and suggestions of surcharges and referees and so on medical men should have it suggested to them that they should cut down prescribing to the very minimum amount. He had never seen or heard of any investigation to find out if medical men were supplying sufficiently good medicines and the tonics and building-up preparations which were often necessary. So long as the medicine was cut down and the cost of prescribing was low there was evidently no worry as to whether the insured person was getting proper remedies. The whole tendency of the system was to cause the doctor to be afraid to give what in many cases would only be adequate for the nature of the case.

Sir R. Hamilton called attention to the enormous value of the work of the Highlands and Islands Medical Service Fund. Since the Fund was instituted in 1913 money values had altered enormously. The Fund was expected to do the same work to-day, when costs were infinitely higher, as it was doing in 1913. In a short time, unless a further contribution was made, the work of the Fund could not be carried on, and it would have to come to an end in 18 months. He had it on the best authority that another £25,000 a year was required. A branch of the work which had been an outstanding success had been the appointment of consulting surgeons in the outer islands.

Mr. Scrymgeour, dealing with venereal disease, said that there was evidence that the Scottish Board of Health would like to do something more, but were being held back by the English Ministry of Health. The Liverpool Bill reached the second reading stage without challenge, but when the Edinburgh Bill came up, it was defeated. The instigation of the Government, on representations from the Secretary for Scotland, was against the Bill.

Sir Archibald Sinclair emphasised what Dr. Shiels had said about harrying doctors for over-prescribing. He asked for an assurance from the Government that the efforts of the local people to maintain and improve the equipment of the Bignold Hospital, in Wick, and the Dunbar Hospital, in Thurso, would be supported, and in particular

that they would be able to obtain the much needed services of a surgeon.

Mr. STEPHEN complained about a paragraph in the report of the Scottish Board of Health dealing with the certification by doctors under the National Health Insurance scheme. He challenged the implied reflection in it that doctors in Scotland were not acting as professional men with the responsibilities which they undertook when they became doctors, and that they were allowing people to draw sick benefit when they were not entitled to it. The experience of those who had to take advantage of National Health Insurance was that, so far from its being easy to get a certificate of ill-health, the tendency was to send people back to work when they were unfit to go. It was obvious that the paragraph in the report was written to try to terrorise the timid members of the profession into sending people back to work before they were fit to return, or to keep them from giving certificates to members of the working classes who, through being unemployed and consequently unable to get proper food, had got into an unhealthy condition.

Reply to the Debate.

Major ELLIOT, Under Secretary of State for Scotland, replying to the debate, said that Mr. Stephen had spoken of reflections and attacks on the medical profession contained in the report. The spectacle of Mr. Stephen defending the medical profession against the attacks of Sir Leslie Mackenzie was one that they might well leave to the delighted laughter of the medical profession in Scotland. There were many houses in Scotland which not only did they regard as unfit for human habitation, but their fathers and grandfathers had also done so, and he sometimes thought the very savages in the fields would also have classified as unfit. Those were the houses that the Board of Health wished to get rid of in the first place, and until they made a beginning with them it was useless to re-classify houses, and say that no houses were satisfactory unless there were three rooms, with bathroom, water closet, and other modern conveniences. They had done their utmost to impress on the local authorities who were building houses that people at present were suffering acutely not only from unsatisfactory houses but from overcrowding. A cut had taken place in the English housing subsidy, but none took place in that for Scotland, and they had the assurance that none would be made until March 31st. In regard to the subsidy for the Highlands and Islands Medical Service, that, again, would have to be considered. It was now £42,000 a year, but the Fund was drawing on its unexpended balances to make up an expenditure of £62,000 a year. The Secretary of State would again approach the Treasury, and he had no doubt that they would succeed in getting a substantial increase in the statutory rate of that subsidy. The report of the Scottish Board of Health was a review of the work of the local authorities. It pointed out many directions in which that work needed to be expanded and in which it could be greatly advantaged by a better system of coöperation among the local authorities. All these things were being brought up, considered, and dealt with in the great financial measures now before Parliament.

The debate was adjourned.

HOUSE OF LORDS.

THURSDAY, JUNE 7TH.

National Health Insurance Bill.

Viscount GAGE, in moving the second reading of the National Health Insurance Bill, said that it was an agreed measure between the two parties chiefly concerned. The criticism which had been, so far, directed against the Bill was not directed against what it did, but what it did not do. The Minister of Health had proceeded on the lines of doing as much as he could to simplify administration, to extend the advantages of medical and other benefits, and also to prevent abuses without giving offence to susceptibilities. Also, he had naturally taken into consideration the very important question of expense, for in the present depressed state of industry he had not considered it advisable to add to the already considerable burdens occasioned by the social services. The noble lord went on to explain the provisions of the Bill. In conclusion, he claimed that the measure would remove many grievances and would simplify administration to a very large extent. The extent to which it encroached on public funds was very small.

Lord GORELL said that he thought that Lord GAGE was putting the case a little high when he said that this Bill was an agreed measure. Technically, perhaps, it was so, but not if that phrase was taken as meaning that those with whom he (Lord Gorell) was associated could in any sense be said to be content with its provisions. No full explanation had been given, either in their Lordships' House or in the House of Commons, as to why the powers of the Minister of Health, with a large Parliamentary majority behind him, were so limited, and why it should not have been possible to take a much bigger view of the whole question of National Insurance. He regretted greatly that there had been no advance at all in regard to specialists' services. He regretted particularly that the great question of maternal mortality had been left wholly untouched. He would have liked to see something more done emphasising the necessity for attendance in maternity cases. The Bill could not be regarded as final; it was a small instalment, an improvement in machinery, and as such he accepted it and was glad to have it placed on the Statute Book.

Earl BEAUCHAMP said he was glad to see that His Majesty's Government now welcomed the institution of national insurance and were anxious to make it an integral part of the national life. He agreed, however, with Lord Gorell that this measure did not go far enough. It only carried out 32 out of the 122 recommendations of the Royal Commission. Adequate justice was not being done to the insured people of this country, and would not be done until the money which had been taken from them had been restored.

Lord COZENS-HARDY said that the Bill, so far as it went, certainly improved the great system of National Health insurance, and for that reason he welcomed it, but he regretted that the Government had not had the courage of their convictions in regard to some of those extensions of medical benefit which on all hands were regarded as urgently necessary. There was one point in regard to Clause 16. Under the present arrangements for medical benefit the insurance committee had to set up statutory subcommittees to investigate complaints concerning the services included in medical benefit, whether relating to doctors or chemists. These medical and pharmaceutical subcommittees did very useful and important work. Complaints of this nature could only be investigated satisfactorily locally, and he trusted that they would have some assurance that provision for similar machinery for investigating complaints in regard to any such local services would be made whether those services were statutory or additional benefits. In particular, he hoped that they would be assured that insurance committees would be required to set up a dental service subcommittee on the same lines as the medical service subcommittee.

The Bill was read a second time.

MONDAY, JUNE 11TH.

Food and Drugs (Adulteration) Bill.

Viscount GAGE, in moving the second reading of the Food and Drugs (Adulteration) Bill, said that it was a measure which consolidated legislation relating to the sale of food and drugs extending over a period of about 50 years.

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 6TH.

Storage of Poisonous Gases.

Lieut.-Commander KENWORTHY asked the Home Secretary what regulations were in force for preventing the storage of poisonous gases near large centres of population, and what steps were taken to prevent their accidental release; if his attention had been drawn to the disaster at Hamburg where a supply of phosgene gas was accidentally released, with many casualties; whether he was satisfied that the regulations in this country were sufficient to avoid any such danger and that those regulations were strictly adhered to; and whether the police had a supply of gas masks available for use in the event of an emergency.—Lieut.-Colonel Sir V. HENDERSON, Under-Secretary for the Home Office, replied: There are no such regulations in force in this country, and the considerable use which is made of phosgene and other poisonous gases in various industrial processes necessitates the storage of these gases in the factories concerned. The precise cause of the Hamburg disaster is not clear, but it is noteworthy that the container at Hamburg appears to have been of much greater capacity, and therefore liable to far greater stress than the containers generally in use in this country. The chief safeguard against accidental release is that the containers should be of adequate strength, and the inquiries my hon. friend has made on this point indicate that the containers in use here have a wide margin of safety and that the position generally is satisfactory. An inquiry, however, into the storage of such gases is at present being carried out by a committee of the Scientific and Industrial Research Department, and it will be necessary to review the situation in the light of their findings. The supply of gas masks to the police will be considered, but on present information this would hardly appear to be necessary.

Mr. THURTLE asked the Secretary of State for War whether any phosgene gas, or gas of a similar nature, was in the possession of the British Army either at home or abroad.—Sir L. WORTHINGTON-EVANS replied: Certain small quantities of phosgene and similar compounds are kept by the Army for use in research and experimental work.

Slum Clearances in Wales.

Sir ROBERT THOMAS asked the Minister of Health whether any local authority or authorities in Wales and Monmouthshire, other than Welshpool Town Council, had put forward schemes for slum clearance, and on what grounds in each case the schemes were rejected by his department.—Sir KINGSLEY WOOD replied: No schemes have actually been submitted by any other local authority; I am aware that the urban district council of Pontypool and the town council of Merthyr Tydfil have had such schemes under consideration; the former council deferred their scheme in order to concentrate on the erection of new houses, and in the latter case the present financial position of the council has led to the deferment of the scheme.

THURSDAY, JUNE 7TH.

Motorists and Excessive Noise.

Sir ROBERT THOMAS asked the Home Secretary how many motorists were prosecuted for excessive noise during the last six months of 1927, and up to the present date this year.—Sir WILLIAM JOYNSON-HICKS replied: The number of prosecutions in the Metropolitan Police District for excessive noise during the last six months of 1927 was 1622, and from Jan. 1st to April 30th, 1928, inclusive, was 4150.

Coroners and Instructions to Juries.

Mr. MALONE asked the Home Secretary whether, in view of the instruction given by the coroner to the jury at the inquest on a recent case where death was found to have been due to poisoning—namely, that they must name some person as having administered the poison in order that there might be further inquiry, and in view of the fact that another coroner gave a completely contrary instruction to the jury in similar circumstances, so that an open verdict was returned, he would consider the introduction of a measure to define more clearly the instructions to coroners for advising juries in cases of this sort.—Sir WILLIAM JOYNSON-HICKS replied: It would be wrong for me to comment on the discharge by any judicial officer of his judicial functions, but I am bound to say that I do not think that the effect of the coroner's directions is correctly stated in the first part of the question. In any case I see no reason as at present advised for considering any amendment of the law on this point.

Nursery Schools.

Mr. TREVELYAN asked the President of the Board of Education whether steps had been taken to encourage the provision of nursery schools, and what was the Board's policy in this respect.—Lord EUSTACE PERCY replied: The Board's policy in this, as in other matters, is that laid down three years ago in Circular 1358—i.e., "to ask all local authorities to consider the more immediate needs of their areas in all grades of education, and to formulate programmes of action covering a definite period." Local authorities are now engaged in carrying out programmes formulated in accordance with this policy, and covering the three years 1927–30. This policy is based on the principle that each local authority is best able to judge the relative urgency of different proposals for educational development in its own area, and that pressure from the Board in favour of particular proposals is more likely to retard educational development than to advance it. Since last year the Board have approved proposals for three new nursery schools.

Water-supply in Schools.

Mr. WELLOCK asked the President of the Board of Education whether steps had been taken to secure the supply of hot water in public elementary schools, more especially in infant departments.—Lord EUSTACE PERCY replied: The Board fully recognise the desirability of providing a supply of hot water, especially in infants' schools, and it is their practice to suggest that it should be provided in all cases where it appears reasonably practicable to do so.

Mr. TREVELYAN asked the President of the Board of Education whether he had obtained the names of those schools referred to on p. 71 of Sir George Newman's report on the Health of the School Child for the year 1925, as being entirely without any water-supply, and what steps he had taken to require a water-supply to be provided in them.—Lord EUSTACE PERCY replied: I have obtained the names of the Nottinghamshire and Herefordshire schools referred to. A number of the schools are included in the Black List survey, and in some cases a water-supply has now been laid on. In the large majority of the cases a supply of water, though not actually laid on to the school, is available in the immediate vicinity, often in adjoining premises, and there are very few cases where water has to be carried from any distance. The right hon. gentleman will, moreover, realise that the water-supply at a village school very frequently depends upon the supply available for the village generally, and cannot be dealt with by the school authorities as a separate problem.

Medical Benefit to Aged Friendly Society Members.

Mr. SMEDLEY CROOKE asked the Minister of Health if his attention had been drawn to the effect of the discontinuance of the State grant in aid of medical benefit to aged friendly society members, and whether, in view of the comparatively small amount involved, he would give the matter further consideration.—Mr. CHAMBERLAIN replied: The total amount of the grant in question was less than £1000 in 1926 and was rapidly diminishing. The money had to be distributed amongst any of the 7000 approved societies and branches which had any members who were permanently disabled on July 15th, 1912, and the average amount payable to any society or branch was less than 10*s*. The distribution of these trifling sums involved considerable work on the part of the societies concerned and of my department, the cost for which far exceeded the total sum to be distributed. In these circumstances I have come to the conclusion that the continuance of the grant is not justified. This decision has been communicated to the Consultative Council, on which approved societies of all types are represented, and has received their concurrence.

Report of Committee on Vaccination.

Dr. VERNON DAVIES asked the Minister of Health if he had received the report of the committee appointed to inquire into vaccination, and if this report would be available for members of the House.—Mr. CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. This report will be published shortly as a command paper.

Discharge of Crude Sewage into a River.

Mr. WARDLAW-MILNE asked the Minister of Health whether his attention has been called to the fact that quantities of fish had been recently killed in the River Penk owing to the action of the corporation of Wolverhampton in discharging crude sewage into that river; whether a certificate was granted to the corporation by the Ministry of Health authorising that proceeding; and, if so, upon what grounds that was done.—Mr. CHAMBERLAIN replied: I am aware of this matter. A certificate was granted under a local Act of 1891 by an inspector appointed by me, but under the Act, on his own responsibility. There is an appeal to me; and an appeal has, in fact, been received and is under consideration. I may add that the certificate did not authorise the discharge of crude sewage.

Local Authorities and Food and Drugs Act.

Dr. VERNON DAVIES asked the Minister of Health if he was aware that the medical officer of health or sanitary inspector of many local authorities did not appreciate the fact that they were entitled to procure samples of food and drugs under the Sale of Food and Drugs Acts for analysis, and, if found to be adulterated, prosecute the offender, although these officers might not be the usual authority for the administration of these Acts in their area; and if he would draw the attention of all local authorities to their powers in this respect.—Mr. CHAMBERLAIN replied: I will bear my hon. friend's suggestion in mind.

Committees on Silicosis.

Mr. KELLY asked the Home Secretary the number of committees set up in Great Britain to deal with cases of silicosis and for deciding the payment of compensation to workers incapacitated by silicosis.—Sir WILLIAM JOYNSON-HICKS replied: I assume the hon. Member refers to the Joint Committee set up under the Refractories Industries (Silicosis) Scheme. There are seven such committees. In reply to further questions the Home Secretary said that an inquiry into the pottery industry was taking place, but that notice would be required before he could say anything about silicosis among brickmakers.

Vaccination Statistics.

Mr. SHEPHERD asked the Minister of Health if he would furnish a return showing the number of infants vaccinated per cent. of the births for the past five years in Newcastle-on-Tyne, Birmingham, Manchester, Liverpool, Sheffield, Bradford (Yorks), Leeds, Warrington, and Darlington.—Mr. CHAMBERLAIN replied: Figures for 1927 are not yet available, but the following statement gives the number of births registered, and the number and percentage of these successfully vaccinated, in each of the years 1922 to 1926. In some cases the figures include those for areas outside the county boroughs mentioned in the question which are

situated within the same vaccination officer's district, as separate figures for these areas are not given in the vaccination officer's return.

Area.—(A) Newcastle-upon-Tyne C.B.; (B) Birmingham C.B. (with Perry Barr U.D.); (C) Manchester C.B. (with Failsworth U.D.); (D) Liverpool C.B. (with part of Sefton R.D.); (E) Sheffield C.B. (the part within Sheffield Union); (F) Bradford C.B. (with Clayton, Denholme, and Drighlington U.D.'s); (G) Leeds C.B.; (H) Warrington C.B.; (I) Darlington C.B.

Vac. = Vaccination.

FRIDAY, JUNE 8TH.

Maternal Mortality in Kensington and Southwark.

Mr. DAY asked the Minister of Health whether he was in a position to give the number of deaths per 1000 of the population which had occurred under the head of maternal mortality during the last available periods in the boroughs of Kensington and Southwark respectively.—Mr. CHAMBERLAIN replied: The provisional numbers of deaths classified as due to childbirth for the Metropolitan Boroughs of Kensington and Southwark in 1927 amounted, respectively, to rates of 0·034 and 0·049 per 1000 of the population of those boroughs. The corresponding rates, according to the more usual calculation per 1000 live births, were 2·26 and 2·57 respectively.

MONDAY, JUNE 11TH.

Tuberculosis Patients and Vaccination.

Mr. THOMAS WILLIAMS asked the Minister of Health if he was aware of cases in which sufferers from tuberculosis had been precluded from receiving sanatorium treatment unless the patient consented to be vaccinated; and whether he had sanctioned regulations to that effect.—Sir KINGSLEY WOOD replied: The answer to both parts of the question is in the negative.

Mr. WILLIAMS asked if the right hon. gentleman was aware that in the West Riding of Yorkshire it was said that some regulation existed which precluded a person suffering from tuberculosis from entering a sanatorium unless he was vaccinated, and if he would make inquiries.

Sir KINGSLEY WOOD replied in the negative. He said he would want something far more definite than what some one said in some part of the country. If Mr. Williams had any definite information he would inquire into it.

Mr. WILLIAMS asked if he was to understand that the Ministry was not responsible for a regulation of that kind.

Sir KINGSLEY WOOD: I have just said so.

TUESDAY, JUNE 12TH.

Pharmacists in the R.A.M.C. Territorial Units.

Sir WILFRID SUGDEN asked the Secretary of State for War whether any steps had been taken to secure the services of pharmacists in Royal Army Medical Corps Territorial units.—Sir L. WORTHINGTON-EVANS replied: Provision for the enlistment of dispensers is made in the Establishments of Field Ambulances and General Hospitals of the Territorial Army.

Sir W. SUGDEN asked if these pharmacists were invited or desired to serve in the Royal Army Medical Corps.

Sir L. WORTHINGTON-EVANS replied that they certainly would be eligible if they desired to enlist.

Storage of Drugs and Medical Supplies in the Army.

Sir WILFRID SUGDEN asked the Secretary of State for War at what time in their military career quarter-masters of the Royal Army Medical Corps received instruction in the storage of drugs and medical supplies in such a manner as to prevent waste and deterioration; whether they were at any time subjected to an examination on this subject; and, if so, what steps were taken to ensure that the examiners themselves possessed an intimate knowledge of the storage of drugs and medicines.—Sir L. WORTHINGTON-EVANS replied: Drugs and medical supplies are only stored in military hospitals in quantities sufficient for approximately the current six months' requirements. Instruction in their storage is given as part of the course of dispensing which all soldiers of the Royal Army Medical Corps have to pass before attaining the rank of sergeant. The examination at the end of the course is conducted by a board of medical officers.

New Medical Evidence and Pension Appeals.

Lieut.-Colonel THOM asked the Minister of Pensions what was the procedure by which new medical or other evidence which was not before a pensions appeal tribunal on the hearing of a war pension claim, and which, had it been before the tribunal, would or might have resulted in a decision different from that arrived at, was brought to the notice of the tribunal; and whether the claimant in such circumstances was given an opportunity before the tribunal of leading and being heard on, and having his claim reconsidered in the light of, such new evidence.—Lieut.-Colonel STANLEY replied: The decision of an Appeal Tribunal is, by Statute, final, and the provisions of the War Pensions Act, 1919, do not admit of a re-hearing by the Tribunal of cases once decided. As, however, the House has on more than one occasion been informed, the Ministry have been enabled, in exceptional cases where fresh material evidence is produced, to reconsider the claim. If such evidence is produced in a case where an appeal has been made and has failed, it is their practice to consult the President of the Tribunal informally before making any recommendation for a grant, in order that no point in favour of the claimant may be overlooked.

Final Pension Awards.

Mr. ROBINSON asked the Minister of Pensions if he would issue life pensions at the current rate to all pensioners in receipt of an award for 12 months, and until further instructions, who had not made an application for treatment since the issue of the award.—Lieut.-Colonel STANLEY replied: I agree with the hon. Member as to the desirability of making final awards in all cases as early as possible, but it would not be justifiable, nor would it be in the interests of pensioners, that such awards should be made on the lines suggested by the hon. Member without proper medical consideration of the individual cases.

Specialist and Consultant Service on National Insurance.

Mr. HORE-BELISHA asked the Minister of Health whether he was now in a position to make a statement regarding the recommendations of the consultative council in respect of the proposals made by the Royal Commission on National Health Insurance that the scope of the benefit should be extended to include a consultant and specialist medical service, and that the necessary funds for this purpose should be obtained by a partial pooling of future surpluses of approved societies.—Sir KINGSLEY WOOD replied: The recommendations of the Royal Commission, to which the hon. Member refers, were very fully considered by the consultative council, who unanimously endorsed the recommendation that the first extension of the statutory benefits of National Health Insurance should take the form of the widening of the scope of medical benefit to include a specialist and consultant service. The Council, however, by a large majority, declined to endorse the recommendation of the Royal Commission that the cost of this extension should be met by means of a partial pooling of future surpluses of approved societies.

CASUALTIES AND OUT-PATIENTS AT THE LONDON HOSPITAL.—At the recent Court of Governors it was reported that the number of minor casualties treated during the past quarter was 5971, as compared with 11,289 in the corresponding quarter of last year. The fall is due to the policy of discouraging the attendance in the receiving-room of patients suffering from very minor ailments who are well able to pay for private treatment. It has been decided to alter the charge to out-patients in a position to pay to a uniform amount of 1s. for a week's treatment, including dressings, X rays and medicine. The poorest patients will, however, still be treated free. The amount received for the quinquennial appeal is now £79,000.

Obituary.

WILLIAM ALEXANDER YOUNG, M.B. ST. AND.

HARD upon the tragic death from yellow fever of Hideyo Noguchi, which occurred on May 21st at Accra, comes the sad information that the same disease has carried off William Young, the Director of the Medical Research Institute of the Gold Coast. The tragedies may well be connected, as it seems probable that Dr. Young incurred the fatal infection when making a post-mortem examination of Prof. Noguchi. William Young, although he received his education entirely in Scotland, was a Londoner, and was born in 1889 in Fulham. He was educated at Forfar Academy and University College, Dundee, the medical school affiliated to the University of St. Andrews, and graduated in medicine and surgery in 1911. Returning to England, he was appointed house physician at the Royal Infirmary, Halifax, and held a further house appointment at the Seamen's Hospital, Greenwich, after which he acquired the diploma in tropical medicine and hygiene at the University of Liverpool. In 1913 he received an appointment in the West African Medical Service, and the war found him at his post in Sierra Leone. He immediately took a commission in the R.A.M.C. and served throughout the war, mainly in the Cameroons campaign. On the cessation of hostilities he was appointed assistant bacteriologist at the Medical Research Institute in Nigeria, where he was soon recognised, both by the work that he did and his written accounts, as an accurate diagnostician and a really scientific bacteriologist. The pathology of many tropical diseases—blackwater fever, trypanomiasis, and yellow fever especially—was studied by him intensively, as the various circumstances of their epidemicity and endemicity came before him, and his contributions to the transactions of the Royal Society of Tropical Medicine and Hygiene were always thoroughly well informed. His keen sense of proportion may be seen in his work on the bacteriology of Sierra Leone waters which appeared in this journal, and in many other contributions to the same pages. He was appointed Director of the Medical Research Institute at Accra some three years ago, and all workers in the field which Young had made his own regarded him as an observer from whom the finest results might be obtained, and know well the loss inflicted upon their school of investigation by his death in the prime of life.

Outside his professional work Dr. Young was known for his interest in model engineering, while he was a particularly expert swimmer.

KENNETH ALEXANDER MACLEAN, M.B., CH.B. EDIN.

WE regret to record the premature death of Dr. Alexander Maclean, which occurred recently on the Gold Coast, where he was in private practice. He was educated at the University of Edinburgh, where he graduated M.B., Ch.B. in 1910, when he came to practice in London, becoming assistant medical officer to the Paddington and Kensington Tuberculosis Dispensary. On the outbreak of war he took a commission in the R.A.M.C. and served with the 54th Division in Gallipoli. In 1916 he was appointed bacteriologist at Ismailia, and he remained working at this station until the middle of 1919, when he took up practice at Seccondee on the Gold Coast. Here, as might be expected of a man of tried professional ability, with a real insight into scientific medicine and a sound working knowledge of laboratory methods, he promptly made a position for himself. He conducted a private hospital and had a large practice amongst natives as well as Europeans, and while by his patients he was universally respected for his skill, his kindliness and generosity were always in evidence. His name further will be remembered on the West Coast of Africa as being the first observer to detect and prove microscopically that in a recent outbreak in the Ashanti gold fields the disease to be dealt with was plague.

Dr. Maclean had been for over eight years in Seccondee, and his untimely death from heart failure is a loss to medicine, to his friends, and to the Colony.

Medical News.

UNIVERSITY OF OXFORD.—At a Congregation on June 9th the degree of Doctor of Medicine was conferred (*in absentia*) on W. F. Skaife.

UNIVERSITY OF CAMBRIDGE.—Mr. J. B. Buxton, F.R.C.V.S., has been re-elected to the Chair of Animal Pathology.

UNIVERSITY OF LONDON.—At recent examinations the following candidates were successful:—

THIRD (M.B., B.S.).

Honours.—D. S. M. Barlow (*c*), Univ. Coll. Hosp.; H. I. Deitch (*d*), Middlesex Hosp.; Emma J. King (*c*), London (R.F.H.) School of Med. for Women; T. Morton (*a*), St. Thomas's Hosp.; H. J. Seddon (*b, d, e, University Medal*), St. Bart.'s Hosp.; F. R. Stansfield (*a*), Univ. of Leeds; and H. C. Trowell (*b*), St. Thomas's Hosp.

(*a*) Distinguished in Medicine; (*b*) in Pathology; (*c*) in Forensic Medicine; (*d*) in Surgery; (*e*) in Midwifery.

Pass.—F. W. Allinson, Univ. Coll. Hosp.; S. W. Allinson, Univ. Coll. Hosp.; I. Bakhsh, Guy's Hosp.; A. Bonnard, Univ. Coll. Hosp.; Irene F. Callender, St. Mary's Hosp.; M. Carpenter, Univ. Coll. Hosp.; Doris B. Clay, London (R.F.H.) School of Med. for Women; K. M. Cobban, Univ. of Liverpool; M. Coleman, Univ. Coll. Hosp.; N. E. Cook, St. Bart.'s Hosp.; J. N. Cumings, King's Coll. Hosp.; Constance M. Cusden, Charing Cross Hosp.; S. Davies, Univ. Coll. Hosp.; Jessie Edwards, Charing Cross Hosp.; Marguerite M. Fenn, London (R.F.H.) School of Med. for Women; G. M. FitzGibbon, St. Thomas's Hosp.; Dorothy D. Forster, St. Mary's Hosp.; F. Forty, Univ. Coll. Hosp.; Mary Fraser, London (R.F.H.) School of Med. for Women; P. J. Ganner, Univ. of Birmingham; Yetta Gimpelson, St. Mary's Hosp. and London (R.F.H.) School of Med. for Women; Barbara M. L. Glover, London (R.F.H.) School of Med. for Women; E. D. Y. Grasby, Guy's Hosp.; A. C. Hancock, Guy's Hosp.; J. C. Hawksley, Univ. Coll. Hosp.; R. A. Hill, St. Thomas's Hosp.; T. H. Hobbes, St. Bart.'s Hosp.; L. Holmes, St. Bart.'s Hosp.; Effie L. Hutton, London (R.F.H.) School of Med. for Women; Morfydd R. Jones, London (R.F.H.) School of Med. for Women; A. B. Kettle, Guy's Hosp.; M. C. Lavin, London Hosp.; Flora W. Lloyd, St. Mary's Hosp.; M. F. B. Lynch, London Hosp.; A. R. Macdonald, St. Bart.'s Hosp.; A. M. McMaster, St. Bart.'s Hosp.; E. H. Madge, Univ. Coll. Hosp.; M. L. Maley, St. Bart.'s Hosp.; Muriel M. Manley, London (R.F.H.) School of Med. for Women; A. N. T. Meneces, Univ. Coll. Hosp.; Mary M. Moller, London (R.F.H.) School of Med. for Women; R. H. Morley, Univ. of Leeds; E. G. Muir, Middlesex Hosp.; J. W. Notley, Univ. of Birmingham; Lois J. Ogle, London (R.F.H.) School of Med. for Women; Evelyn D. Owen, Charing Cross Hosp.; J. R. Pierre, Univ. Coll. Hosp.; E. S. Phillips, Guy's Hosp.; R. F. Phillips, St. Bart.'s Hosp.; A. M. Richards, Univ. Coll. Hosp.; Audrey E. Russell, Univ. Coll. Hosp.; J. E. Saville, St. Thomas's Hosp.; Thelma Shepherd, London (R.F.H.) School of Med. for Women; Gwladys V. Smallpiece, London (R.F.H.) School of Med. for Women; R. S. Smith, Univ. Coll. Hosp.; K. H. Southall, Univ. Coll. Hosp.; C. A. Stanley, St. Thomas's Hosp.; Mary M. Tulloch, Charing Cross Hosp.; and C. L. Worthington, Guy's Hosp.

Supplementary Pass List.—The following students have passed in one of the two groups of subjects:—

Group I.—Sophia Antonovitch, London (R.F.H.) School of Med. for Women; A. L. Basham, St. Thomas's Hosp.; A. C. H. Bell, St. Bart.'s Hosp.; Ruth Bocock, London (R.F.H.) School of Med. for Women; W. P. M. Davidson, St. Bart.'s Hosp.; Helena M. de Hartog, St. Mary's Hosp.; Marjorie M. Dobson, London (R.F.H.) School of Med. for Women; Dorothy V. Dunolly, Univ. of Durham; Dorothy E. Eglington, London (R.F.H.) School of Med. for Women; Geraldine W. Everett, London (R.F.H.) School of Med. for Women; G. S. Ferraby, King's Coll. Hosp.; C. Gross, Guy's Hosp.; Helen M. Herbert, London (R.F.H.) School of Med. for Women; Alice D. M. Hodge, London (R.F.H.) School of Med. for Women; E. C. H. Huddy, Guy's Hosp.; D. F. Kanaar, Guy's Hosp.; C. F. Moore, St. Bart.'s Hosp.; Mary E. Pease, Univ. Coll. Hosp.; G. C. Pether, Middlesex Hosp.; Gwynedd M. Phillips, King's Coll. Hosp.; Edith J. L. Smith, London (R.F.H.) School of Med. for Women; E. R. Smithard, Middlesex Hosp.; and E. S. Vergette, St. Bart.'s Hosp.

Group II.—Mabel A. Baker, London (R.F.H.) School of Med. for Women; S. Bernstein, Univ. Coll. Hosp.; S. J. M. De Navasquez, Guy's Hosp.; D. E. Dunnill, Guy's Hosp.; H. Evans, London Hosp.; R. V. Farr, Univ. of Birmingham; A. McK. Fleming, Middlesex Hosp.; W. H. George, London Hosp.; J. H. F. Jayasuriya, Ceylon Med. Coll. and Middlesex Hosp.; I. J. Jones, St. Thomas's Hosp.;

Gladys E. McCabe, London (R.F.H.) School of Med. for Women and St. Mary's Hosp.; M. Mackenzie, Guy's Hosp.; H. Mannington, Middlesex Hosp.; C. G. MacM. Nicol, Charing Cross Hosp.; G. L. S. Plumbly, Univ. Coll. Hosp.; E. I. Puddy, St. Mary's Hosp.; J. R. Rickett, Guy's Hosp.; I. M. Robertson, St. Bart.'s Hosp.; Clarice A. Skidmore, London (R.F.H.) School of Med. for Women and St. Mary's Hosp.; A. G. Watkins, Univ. Coll. Hosp.; P. C. Wickremesinghe, Ceylon Med. Coll. and Guy's Hosp.; and Elsie E. Wright, London (R.F.H.) School of Med. for Women and St. Mary's Hosp.

UNIVERSITY OF BRISTOL.—At recent examinations the following candidates were approved:—

FINAL EXAMINATION FOR M.B., CH.B.

Part II.—*‖T. H. Berrill, B. J. Boulton, †R. D. Jenkins, *Helen B. Murgoci, and ‡T. B. Wansbrough.

*With distinction in Special Pathology. †With distinction in Public Health. ‡ With distinction in Obstetrics. ‖ With Second Class Honours.

Group II.—D. E. C. Andrew and A. J. M. Grimston.

Part I. (including Forensic Medicine and Toxicology).—Rowena M. Hickman, April D. James, Mabel F. Potter, and *N. L. Price (with distinction in Materia Medica, Pharmacy, Pharmacology, and Therapeutics).

Forensic Medicine and Toxicology only.—Isabella J. Armstrong.

FINAL EXAMINATION FOR B.D.S.

Wynne M. Evans.

DIPLOMA IN DENTAL SURGERY.

J. H. Edwards, H. J. Phillips, and S. M. Weir.

GUY'S HOSPITAL MEDICAL SCHOOL.—At 4 P.M. on June 26th, Dr. Arthur Hopewell-Smith, of the University of Pennsylvania, will give a lecture at Guy's Hospital, entitled The Process of Osteolysis: an Historical Study.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—Sir William Beveridge, vice-chancellor of the University of London, will distribute prizes in the Governor's Hall of the hospital on Wednesday, June 20th, at 2.30 P.M.

LONDON HOSPITAL MEDICAL COLLEGE.—The prizes will be distributed at 3 P.M. on Friday, June 29th, by Sir Samuel Hoare, Secretary of State for Air.

THE Minister of Health has appointed Mrs. Barton, J.P., as an additional member of the Departmental Committee set up to consider the working of the Midwives Acts. (See THE LANCET, May 26th, p. 1104.)

INTERNATIONAL CONGRESS OF OTOLOGY AND LARYNGOLOGY.—At this congress, which opens on July 29th at Copenhagen, speakers will be limited to ten minutes owing to the number of papers which are being presented. The subscription for those attending the congress is 30 Danish kroners, and 15 kroners for each member of the family. Payment should be made to Dr. Jorgen Moller, 13, Vestre Boulevard, Copenhagen K.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, June 19th.—5.30 P.M., GENERAL MEETING OF FELLOWS. Ballot for election to the Fellowship.

THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.) *Cases:* Dr. G. B. Dowling: (1) Dermatitis Vegetans? (2) Unusual Tuberculide. (3) Annular Sarcoid. Other cases will be shown.

FRIDAY.—8 P.M., EPIDEMIOLOGY. Annual General Meeting: Election of Officers and Council. *Paper:* Dr. J. Alison Glover: Some Observations on Nasopharyngeal Infections in Public Schools.

RESEARCH DEFENCE SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY, June 19th.—3 P.M., Sir Bernard Spilsbury: The Work and Responsibilities of a Pathologist (Stephen Paget Memorial Lecture).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, June 18th, to SATURDAY, June 23rd.—CHARING CROSS HOSPITAL, W.C. Clinical demonstration by Mr. E. D. D. Davis in the Ear, Nose and Throat Department on Fri., at 11 A.M.—ROYAL EYE HOSPITAL, St. George's Circus, Southwark, S.E. Clinical demonstration by Mr. Dorrell on Fri., at 3 P.M.—SOUTH LONDON HOSPITAL FOR WOMEN, 88, Newington Causeway, S.E. Clinical demonstration by Mrs. Tindal-Robertson on Wed., at 10.30 A.M. Women only admitted to this demonstration. The above are free.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Special course in Gynæcology; occupying some mornings and some afternoons.—CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E. Special course. Post-graduates can spend the entire day at the hospital.—LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. General Practitioner's course, 4.30 to 6 P.M., Medicine, Surgery, and Specialties. Further particulars from the Secretary (Mayfair 2236).

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

MONDAY, June 18th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

On Wednesday and Friday, at 2.30 P.M., there will also be demonstrations of Eye and Medical (Children) Cases by Mr. N. B. B. Fleming and Dr. C. E. Sundell respectively.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, June 19th.—3.15 P.M., Mr. W. B. Gabriel: Foreign Bodies in the Gastro-Intestinal Tract.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, June 18th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: Out-patient Clinic.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Grainger Stewart: The Diagnosis of Cerebral Tumours (1).

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Bailey: Demonstration of Electrical Methods of Treating Paralysis (in Electrical Room).

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Purdon Martin: Jacksonian Epilepsy.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.

WEDNESDAY, June 20th.—4 P.M., Dr. E. D. Macnamara: Functional Nervous Disorders.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL Gray's Inn-road, W.C.

MONDAY, June 18th.—1.30 P.M., Mr. R. J. Cann: Hearing Tests.

WEDNESDAY.—1.30 P.M., Mr. N. MacKeith: Examination of the Accessory Sinuses.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

TUESDAY, June 19th.—3.30 P.M. (at the Jessop Hospital), Prof. Phillips: Gynæcological Aspect of Contraception.

FRIDAY.—3.30 P.M. (at the Royal Hospital), Mr. Ferguson Wilson: Surgical Cases.

Appointments.

CUNNINGHAM, H. BOYD, M.B., B.S. Durh., has been appointed Ophthalmic Specialist Medical Referee under the Workmen's Compensation Act to County Courts Circuits 1 and 2 (Northumberland and Durham).

MARTIN, MARGARET, M.B., Ch.B., M.R.C.P.E., Hon. Assistant Physician, Edinburgh Hospital for Women and Children.

POWELL, A. T. W., M.B., B.S. Lond., Medical Officer of Health, Scunthorpe, Lincs.

Certifying Surgeons under the Factory and Workshop Acts: PARRY, W. E., M.B., B.S. Lond. (City of London); ROSS, R. S., M.B., B.Ch. Belf. (Accrington); SINCLAIR, J. D. S., M.B., Ch.B. Glasg. (Cornwarth, Lanark); and BURNETT, J. F. M., M.B., Ch.B. Aberd. (Bradford-on-Avon).

Vacancies.

For further information refer to the advertisement columns.

All Saints Hospital (for Genito-Urinary Diseases), Vauxhal Bridge-road, S.W.—Res. Sen. H.S. Also H.S. At rate of £200 and £100 respectively.

Barnsley, Beckett Hospital and Dispensary.—H.P. £140.

Barnstaple, North Devon Infirmary.—H.S. At rate of £150.

Birmingham General Hospital.—Asst. S. £50.

Birmingham University.—Asst. Lecturer in Physiology. Also Asst. Lecturer in Biochemistry. Each £300.

Bombay, Cama and Albless Hospitals.—M.O. Rs.800–50–1000.

Brighton, New Sussex Hospital.—Hon. Asst. Ophth. Surg. Also Hon. Clin. Assts.

Bristol, City and Council.—Consultant Aural S. £2 12*s.* 6*d.* per session.

Bristol Eye Hospital, Lower Maudlin-street.—Hon. Rhinologist.

Bury Infirmary.—Sen. H.S. At rate of £200. Also Third H.S. At rate of £150.

Chester Royal Infirmary.—Hon. Asst. P.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Radiologist. 150 guineas.
Colchester, Essex County Hospital.—Asst. H.S. and Reg. £120.
Croydon General Hospital.—Hon. Anæsthetist.
Dreadnought Hospital, Greenwich,—H.P. and H.S. At rate of £110.
East London Hospital for Children, &c., Shadwell, E. 1.—Surg. to Nose, Throat, and Ear Dept.
Edgware, Redhill Hospital.—Radiologist.
Erith Urban District Council, &c.—M.O.H. £800.
Gloucester, Gloucestershire Royal Infirmary.—Res. Surg. O. At rate of £175.
Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—Cas. Surg. O. At rate of £100.
Hartlepool, Hartlepool Hospital.—H.S. £150–£200.
Hellingley, Sussex, East Sussex County Mental Hospital.—Jun. Asst. M.O. £350.
Hove Hospital, Sackville-road.—Res. M.O. £150.
Hull, Royal Infirmary.—Asst. H.S. At rate of £150. Also Cas. H.S. £130.
Ipswich, East Suffolk and Ipswich Hospital.—Two H.S.'s. Each at rate of £100.
Leeds, Jewish Herzl-Moser Hospital.—Res. M.O. £50.
London, Corporation of.—M.O.H. £1500.
London School of Hygiene and Tropical Medicine.—Research Studentship in Entomology. £250.
Manchester, Ancoats Hospital.—H.S. Orthopædic. At rate of £100.
Manchester City, Education Committee.—Asst. School M.O. £600.
Manchester, Salford Royal Hospital.—H.P. and H.S.'s. Each at rate of £125.
Margaret Hospital for Consumption, 26, Margaret-street, W.—Hon. Asst. P.
Miller General Hospital for South-East London, Greenwich-road, S.E.—H.P. and H.S. Each at rate of £125.
Newark Hospital and Dispensary.—Res. H.S. At rate of £150.
Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. Asst. to Ophthalmic Dept. Also Four Med. Regs. Each £250.
Plymouth, South Devon and East Cornwall Hospital.—Res. Surg. O. At rate of £100.
Poplar Hospital for Accidents, East India Dock-road, Poplar, E.—Sen. Res. O. £200.
Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Asst. Res. M.O. At rate of £80.
Queensland Government, Department of Public Instructions.—M.O. £600–£800.
Reading, Royal Berkshire Hospital.—H.P., First and Third H.S.'s. Each £150.
Royal Army Medical Corps.—Commissions.
Royal London Ophthalmic Hospital, City road, E.C.—Sen. H.S. £150.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. At rate of £100.
Saint Mark's Hospital for Cancer, &c., City-road, E.C.—Res. Surg. O. At rate of £150.
St. Mary's Hospital, W.—Asst. Pathological Chemist. £300.
St. Paul's Hospital for Diseases of the Genito-Urinary Organs, &c., Endell-street, W.C.—H.S. At rate of £150.
South-Eastern Hospital for Children, Sydenham, S.E.—Asst. Res. M.O. At rate of £75.
Swansea County Borough.—Asst. Dental S. £450.
University of London.—External Examinerships.
Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £150.
Westminster Hospital, Broad Sanctuary, S.W.—Sen. Res. and Cas. O. At rate of £104.
Willesden General Hospital, Harlesden-road, N.W.—Res. H.S. At rate of £100.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Chagford (Devonshire) and at Oswestry (Shropshire).

Births, Marriages, and Deaths.

BIRTHS.

ALEXANDER.—On June 7th, at Harley-street, the wife of Dr. J. Browning Alexander, of a daughter.

MARRIAGES.

HAWKINS—BOWER.—On June 9th, at Holy Trinity Church, Brompton, S.W., Benjamin Edward Hawkins, M.R.C.S., L.R.C.P., to Edna Gertrude, only daughter of Mr. and Mrs. J. A. Bower, of Dulwich.

KEITH—NOTCUTT.—On June 7th, at St. Mary's Church, Woodbridge, William Brooks Keith, M.C., M.D., of Redwald House, Melton, Suffolk, to Marion Hetty, elder daughter of Mr. and Mrs. R. C. Notcutt, of Topfields, Woodbridge, Suffolk.

DEATHS.

ARMSTRONG.—On June 5th, at Alexandra-road, Bedford Park, W., Robert Stow Armstrong, M.R.C.S., L.S.A., aged 78.

ASHTON.—On June 9th, James Thornhill Ashton, M.B., C.M., for some years resident at Smedley's Hydropathic Establishment, Matlock.

FOSTER.—On June 8th, at the Radcliffe Infirmary, Oxford, of pneumonia, Edward Cecil Foster, M.R.C.S., L.R.C.P., in his 51st year.

WOOLLETT.—On June 7th, at Kingston House, Newmarket, Sidney Winslow Woollett, O.B.E., M.R.C.S., L.R.C.P. (late Major, R.A.M.C.), in his 72nd year.

N.B.— A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE RELIABILITY OF INFANTILE MEMORIES.

Being the Substance of an Address from the Chair at a Meeting of the Medical Section of the British Psychological Society.

BY J. A. HADFIELD, M.A. OXF., M.B. EDIN.,
CHAIRMAN OF THE BRITISH PSYCHOLOGICAL SOCIETY, MEDICAL SECTION; LECTURER IN PSYCHOLOGY, LONDON UNIVERSITY.

IT is generally accepted by modern psychopathologists that the psychoneuroses date back in their origin to early childhood experiences, forgotten and repressed, at least as regards their predisposing causes. If this is so, it is very important to discover how far those supposed memories correspond to actual experiences, and how far they are products of the imagination. The methods by which we arrive at those experiences are well known—namely, hypnosis or free association. They bring an enormous mass of infantile experience to the surface of consciousness, and this material has been systematised into the various theories of psychopathology. The main objections to the validity of these memories are: (1) That it is impossible for anyone to remember as far back in life as the first or second year. (2) That it is inconceivable that a child could have such thoughts and experiences as are ascribed to him.

It is suggested, therefore, that these visualisations are pure imagination, or have been suggested by the analyst. From one point of view, it does not matter very much whether these early experiences are true or not—provided that the patient gets better. But whilst from the therapeutic point of view it is unimportant, from the points of view of systematic psychopathology and of preventive mental hygiene their truth or falsity is of considerable importance.

There is no a priori reason why memories of infantile life should not be recollected. If we can remember what happened to us at the age of three or four, there is no reason why we should not be able to retain experiences that go back to the age of one or two. An infant of a few days old not only recognises the breast of its mother, which may be regarded as an archaic characteristic, but it may also recognise its bottle, showing that it is capable of retention and memory. These facts confute any argument based on the lack of myelination at this early age. If the baby of a few weeks and months old can remember and retain its experiences, is there any a priori reason why that memory should not be reproduced in later life?

Spontaneous Revival of Infantile Memories.

A medical colleague vividly recalls a fire which occurred when he was eight months old. He says: "In the course of a conversation with my parents, when I was about six or seven years of age, I was told that the house in which I was born had caught fire and had been completely destroyed when I was eight months old. Immediately this was mentioned, I said, 'Oh, yes! I remember.' This was ridiculed by my parents, who informed me that, as I was only eight months old at the time, this memory was quite impossible. However, I said, 'But I do remember, and I can tell you something more about it!' I then proceeded to describe a circular staircase coming round a circular wall, and at the top of this staircase was a landing lit by a window. The window had frosted glass in the centre with coloured panels at the sides. I described the whole place lit up—flames licking the glass panels, which were cracking with a noise like the reports of a pistol. My parents said, 'Yes, that is perfectly true,' but added that I must have imagined it. Since that time I have never seen any photographs of the house, which was completely destroyed. These details were corroborated by both my parents, who said that the fire had reached considerable proportions by the time we had reached this landing, and that within five minutes the whole staircase and floors of the house had collapsed."

We cannot, of course, absolutely exclude the possibility of leakage of information in the interim; but not only did the patient have no recollection of this, but in any case the account would not have included such unimportant details as the frosted glass and coloured panels. Moreover, we should expect, on physiological grounds, that an experience so emotional would produce a lasting impression upon the child's brain.

Memories Recovered by Free Association.

We may group the memories obtained by free association in analysis into three classes: (*a*) Those for which we can

obtain objective evidence. (*b*) Those for which there is no objective evidence, but which are corroborated by similar conditions observable in childhood. (*c*) Those which persistently emerge in analysis and yet can neither be objectively proved nor corroborated.

A man of about 23 was sent to the writer as a case of "bronchial asthma," with a spasmodic cough, choking and feeling of suffocation. In free association—in this case under hypnosis—he recovered an experience as a small child in which he was ill in bed and his mother put something under his face, the fumes of which nearly suffocated him. In reviving this experience he had an attack of suffocation. He had remembered nothing of this incident, nor indeed did he remember it as having actually occurred even when he had experienced it in analysis. I asked him to write to his mother and ask simply whether anything had occurred in childhood in which he had been nearly suffocated. She replied that when he had had whooping-cough she had, as a domestic remedy, put some Friar's balsam on a hot shovel to make him inhale it. But the shovel had been too hot and she thought she would have lost him with the attack of coughing and suffocation which it produced. She added that the green bottle she had used still stood on her kitchen shelf. She said that he must have been under 2¼ at the time, because they had left the house in which the incident occurred when he was that age.

The points to note in this case are that we have objective verification of the truth of the experience; and that, curiously enough, although the patient reproduced this true experience, he had no knowledge nor recollection of its truth even after he had recalled it. Two further proofs of the truth of the story are that in recalling it he felt the whole experience vividly, and that the reproduction of the experience cured him of his asthma.

It stands to reason that only a very small proportion of the "memories" revived from childhood can be objectively verified because of the absence of parents and others who could verify them; because most of the experiences are subjective and therefore cannot be confirmed; and because the most important of these experiences are not only subjective but repressed.

Memories which are Probable but not Verifiable.

The second group are those which we have no means of verifying objectively, but which, nevertheless, may be corroborated by similar experiences commonly observed in child life. This is perhaps the most important and reliable method of determining the truth of our theories as to the origin of the psychoneuroses. All the symptoms of psychoneuroses—hysteria, anxiety states, obsessional fears and neurasthenia, as well as the perversions—may be observed in the normal child. The theories of Freud, of Jung, and of Adler all emphasise the importance of infantile experiences in the production of later abnormalities. It is natural, therefore, that we should look to early childhood itself to determine, first, whether these feelings and thoughts exist in children; and, secondly, whether they are found actually to give rise to the psychoneuroses. A patient says: "I feel myself at the breast sucking comfortably and warm. Then some thing seems to happen, something terrible, like an impending disaster." (Pause.) Pressed to continue, he says: "Well, something ridiculous comes to my mind. I get a taste of blood in my mouth, and then the thought of myself biting my mother—but that can't be true, a baby of that age has no teeth to bite with."

A picture of that kind gives very strong evidence of truth. We may, or may not, get objective evidence for it, but in spite of the patient's disclaimer, we know that such things do frequently happen in infancy, and indeed may necessitate weaning. The very scepticism of the patient as to the possibility of the memory, which is not merely unexpected and actually discredited, but also repugnant to him, adds credence to it.

In hypnosis and in free association there sometimes emerge images representing the emotional experiences of birth. Darwin long since pointed out that the newly born animal expresses all the emotions of fear. Such experiences, as we should expect, seem to leave a lasting impression on the brain, and under special conditions, such as hypnosis, can be reproduced. A patient in a hypnoidal condition suddenly goes off into a state of anxious dread and then begins to experience and describe her feelings just after birth when, as a matter of fact, she was left as dead. She proceeds: . . . "Then all of a sudden somebody snatches me up—falls down on me and takes me up. It is a horrid moment—it came so suddenly. Then it shakes me and I get so frightened and I try to get away from it and try to resist it and I am so terrified! They are *slapping* me. It isn't the pain of it, but the harshness of it—their cruelty. Then I begin breathing and it makes me terrified. I don't think I wanted it. Instead of that greyness, it is all red now, and there is a *terrific* noise everywhere—noise like many waters rushing—terrific noise—no rest, no peace, and they still go on shaking me. Somebody is holding me with a very hard hand, like claws—one on each side of it—so still and cold and cruel and merciless. Then I try to get out of it, *but they are holding me in mid-air—upside down.* But that can't be true; they don't hold babies upside down!"

After the analysis of this experience, I said to her: "Do you not know how they revive infants when they are not breathing after birth?" She said: "I have no idea." I said: "They sometimes take them by the feet upside down and smack them." She said: "Surely that is very cruel!" I replied: "But they think it does not matter because the child has no cutaneous sensations." She said: "But that is just what I experienced; there was no pain at all; but there was terrible shock which made me feel dreadful terror."

It is interesting to note that some obstetricians used to teach students never to slap the new-born child because of the additional shock this inflicts.

Memories Without Reasonable Corroboration.

The third group of memory images are those which can neither be objectively verified nor corroborated by a direct observation of child life, and yet should claim our attention on other grounds, especially their frequency and persistency.

A patient felt very sick when she arrived in the consulting-room—a sickness which had come on after the previous analysis. Told to associate on this feeling, she said: "It's something to do with breasts. Something made me feel that mother's breasts were repulsive. I've got an idea of it now—oh! I hate telling you! Something about this enema business. When I was lying waiting to have it done—I was on the bed—mother must have gone out for something and left me lying there. I'm wondering whether father came—or he was there. Oh! I don't know how I can bring myself to say it—and while I was amusing myself playing with my body—father came up and looked at me in a smirky kind of way. Then he felt me all over, too. He gave me a good deal of pleasure. . . . Something happened one night when she was feeding me. (Feel that.) Father came in and he was in a nasty temper. She said: 'You're drunk'—something in the word 'drunk' used to make me shudder. I used to have nightmares of drunken men coming down on the house. He probably seized her breast and tried to stuff it up against my face. (Movements of repulsion, turning over in distress.) And he said: 'Feed your brat.' Then he called her nasty sort of names—'old cow' and 'bitch,' and mother was terrified and was crying. When he went away she tried to make me finish—to keep on—and that is what made me feel sick. She is trying to put the breast to my mouth. I'm frightened and disgusted and I'm sick—I vomit. Then mother gets fussed because I'm sick over everything." (Patient now much more relieved in tone of voice.)

From the scientific point of view, these pictures are, of course, not on such secure ground as those which can be confirmed, or corroborated by our knowledge of child life, and should be accepted with greater reserve. The main possibilities of such a "memory" are: (1) that it is entirely and literally true, an exact reproduction of the thoughts and experiences of the time; (2) that the whole thing is pure imagination; (3) that it is a real earlier experience, read and interpreted in the light of later experience.

(1) Many of the visualisations in free association admittedly have no objective relation to fact, and no analyst claims that all these pictures are literally true. That should be sufficiently obvious to those who remember that Freud himself discovered long ago that the supposed sexual traumata were not always objectively true, but often turned out to be sexual phantasies.

Sometimes the pictures are symbolic, as when a girl sees herself at the age of 3 in a field of corn and all the heads of corn burst into flame. Again, there are corrections, as when a patient sees herself as a child petting and comforting a doll, and afterwards realises that it was not a doll, but herself, she was comforting. Again, there may be pictures which on the face of them are contradictions—as when a patient sees himself as a child of 2 in a garden where he did not live till he was 5. In such cases, however, it nearly always turns out that the picture is a composite one, combining two experiences of similar emotional tone. Obviously, then, all the pictures in analysis cannot be accepted as literally true.

(2) Nor, on the other hand, can we accept the easy explanation that they are all false.

The first evidence is that of subjective conviction. There is a warmth and intimacy about such experiences which is not present in others. Patients "remember" then as we remember the events of yesterday, and analytic memories should carry at least the same weight of conviction as those of ordinary life.

Another striking feature of the recovery of early memories is the extraordinary emotional tone in which they are revived. The feeling of intense cold, of horror, of anger

is impossible to convey in print, but commands conviction. A case in point is that of a man suffering from a sexual fetichism. In analysis he was carried back to the sensuousness of infantile life. In recovering this experience he became so dissociated that he started to go through all the movements of sucking and continued for two or three minutes. Then he had a short rest and started again and went on till he had had his ten minutes' feed. He then fell back, as it were, with the bloated appearance of the gratified infant. This experience happened on two or three occasions, and after each he would emerge again into ordinary conscious life with a look of surprise. In this mental phase he had completely returned to the feelings and actions of infantile life. The fetichism was directly connected with this experience, and was a symbolic representation of it.

Production and Cure of Symptoms.

During the course of analysis, new symptoms arise. The patient comes feeling quite gay and cheerful, but in the restoration of some buried experience he begins to get depressed, to feel hatred, acute nausea, headache, or any other physical symptom for which he is being treated. One patient, recovering a memory of fear, gets an intense ache in her jaw and neck; another feels so sick he needs a receptacle. Another patient finds herself compelled to make kissing movements the whole evening after treatment. Nor is this a matter of chance, for each time we recover that incident we elicit the same response. Like the dentist probing a tooth, we touch one spot or complex which brings the symptom to the surface. The law of cause and effect compels us to connect the original incident and the present symptom.

The elucidation and liberation of these early incidents brings about cure—a "cure," of course, being for our purpose merely one form of reaction.

A patient was suffering from severe abdominal pains and tremendous distension, so acute that if she ate any food after dinner she was unable to sleep at all owing to the distension. She had, of course, had her appendix removed, but without effect. Ultimately she came in analysis to an experience of infantile life when her mother, usually very tender and gentle with her, appeared to be bathing her very roughly, which made her annoyed and angry. Her mother then gave her her food out of a bottle in a rough way so that the child was unable to digest the food and suffered from very severe wind. It was the acute pain and distension of this that in after years reappeared as her hysterical symptom. When the patient realised that this roughness on her mother's part was not due to any lack of affection, but probably to the fact that the father had recently become a drunkard and the mother was probably impatient to go out and bring him back from the public-house, the symptoms entirely disappeared and have now been absent for some years.

The cure of the symptom cannot be the result of mere suggestion, for in many cases actual suggestion had been tried in vain, and many other similar experiences were revived without effect before we came to the particular one, which, when liberated, left the patient cured for good.

(3) The third possibility is that these pictures are a mixture of real infantile experiences with later interpretations, which may be true or false. A difficulty in the acceptance of such infantile memories is that both in form and substance they seem to be alien to what we already know of child life. They are expressed in language so sophisticated and consist of thoughts so complex and elaborate that it is difficult to believe that they can be reproductions of childhood experiences. In a case mentioned, the patient, remembering what happened in her first year, says, for instance: "While I was amusing myself playing alone with my body, father came up and looked at me in a smirky sort of way." How can an infant understand what a "smirk" is? How, in the birth phantasy, could an infant know that it was upside down? How could it know what strangulation meant? It is quite true that a baby cannot know these things, but it can feel them, and these experiences may leave a deep impression on the mind. A baby, it is true, cannot know that it is upside down, because for a baby there is no "up" and no "down"—in which it proves itself a better philosopher than we—but a child can feel that it is upside down, and soon lets you know it. A child may not know what bitterness is, but it can taste bitterness. A child cannot know that it was strangulated, but it can feel strangulation, and the reproduction of this feeling was actually experienced.

A large part of our difficulty disappears if we keep in mind these facts: (1) That a child's mental experiences consist almost entirely of undifferentiated feelings which only later become differentiated into thoughts. (2) That it is possible to reproduce feelings as well as thoughts. (3) That if these feelings are to be expressed at all in later life, they must be expressed in language which is necessarily sophisticated and mingled with a certain amount of interpretation, true or false.

The Nature of a Child's Experience.

The mind of a child probably consists of vague and undifferentiated feelings—longing for food, craving for gratification, feelings towards its mother. It is only later that these become differentiated out into thoughts Thoughts, as Conrad says, are the shape that feelings take, and the child has feeling experiences even when it cannot shape these feelings into thoughts. These feelings are very complex and complete, and contain all the embryonic material which will later find shape. The simple infantile experience of crying when thwarted in its desire to be at the breast is simple and undifferentiated; it is just one experience. We may, nevertheless, find in it elements of several forms of mental experience. There is anger; there is misery; there is sensuous desire; there is hope; there is despair; there is effort; there is abandonment and futility. The experience itself is simple and undifferentiated, but as he recalls this experience and revives the feeling in later life, the patient may analyse it and find in it all these elements. I would venture to say that there is no feeling or emotion of the adult which the infant is not capable of experiencing. The difference between the infant's mind and that of the adult is that in the former these feelings are vague, crude, and undifferentiated, whereas in the adult they are differentiated and formed into definite cognitions. A child can experience where it cannot understand; it can feel where it cannot discriminate; it lives by its feelings, not by its thoughts. In this way, a child appears to be extremely sensitive to the moods and feelings of those around it. The child can easily feel the anger of its father without being able to think, "there's father upset again!" It can feel jealousy towards another child without being able to discern that "the other child is standing in my way." A child can cling to its mother for protection without being able to realise "if I get separated from her it's all up with me!" The infant is terrified by noise without being able to recognise that noise spells danger. An infant may hear the sound of a word, such as "drunk" (in our illustration), and retain it, with considerable emotional tone, without the word being really understood, and yet the reproduction of the word would reproduce the unpleasant feelings associated with it. The failure to appreciate the way in which a child feels experiences, even when it cannot understand them, has led to pitiable blunders on the part of parents, who permit their children to witness sights and undergo experiences on the ground that they are "too young to understand." Undoubtedly, they are "too young to understand" the whole significance of such acts, but they are not too young to feel, and experiences that are not in the least understood by a child may produce violent commotion in its soul. Indeed, it is very often these experiences which, for the very reason that they are not understood but strongly felt, produce such a profound effect upon the mind. If we remember this we can realise how it is possible for these experiences which come up in analysis to be real experiences of early childhood, even though the thoughts into which they are differentiated, and the language in which they are expressed, belong of necessity to a later age. This view is supported by anatomical observations. In the year-old child the thalamus, the centre of affect and emotion, is active, whereas the cortex, the centre for more discriminative thought, is probably not in full function.

Translation of Feelings into Language.

Memory is conscious reproduction, and it is just as possible to reproduce a feeling in consciousness as it is to revive a thought. A patient can revive a feeling of depression and give vent to a fit of sobbing without reference to any present cause of cognitive content. This is precisely the way in which pictures often come in analysis; first the feeling and then the cognitive content. The infant, of course, cannot express his feelings in any other way than by emotional expression. The adult, on the other hand, recovering these same feelings in analysis may at first be incapable, like the child, of doing anything but feeling them, but later he becomes capable of putting the feelings into words. The result may be a perfectly true interpretation of his infantile experience, though the language and thought is far too sophisticated for a child to enunciate or even to think. The argument, therefore, that these memory pictures of childhood are not true because they are much too sophisticated is not conducive, for the child undoubtedly has feelings and, if feelings are to be expressed at all, it must be by words. In that transformation of the early experiences into adult thought and language there is, of course, always an element of interpretation, analagous to the secondary elaboration which takes place in dreams. We are faced with three possibilities: (1) A simple and accurate translation of these feelings into language. (2) Interpretation in the light of later experience, and the interpretation, nevertheless, may be a correct explanation of the feeling. (3) Incorrect interpretation too much influenced by later experience.

When the child feels a sense of awful dread in infancy and the adult expresses this in analysis, he is merely translating real feelings into words. In the incest phantasy, we may assume that the child is not conscious of any knowledge of sexual intercourse any more than it is aware of the idea of hunger or of death. This may, nevertheless, be what it feels and desires—an archaic feeling handed down with its physiological inheritance—if it could put its wishes into words. That is one view of the case.

In the second place, it may be that the child has certain feelings which we know and understand to be inherently sexual, and we may be right in so interpreting them. The girl, in later adolescence, may have cravings and desires of which she does not understand the nature, but which are quite clearly sexual and which she later recognises as such. We should be quite correct in so interpreting them. So the child may have precisely such feelings and cravings, and we may be quite right in interpreting his cravings as sexual. These feelings would not be understood at the time, but the adult patient, recovering the experiences, would understand and interpret them in the light of later experience.

On the other hand, it may be that the sensuous experiences are true, but the interpretation is false. It may be that the child has certain experiences of a sensuous kind which may be really egoistic, but, because they are so similar in feeling to later sexual feelings, they are wrongly interpreted as sexual.

This question of the interpretation of early experiences is a very important one, because upon it depend the various schools of psychopathology. There is a certain agreement as to the facts, as there must be to those who get free association in childhood, but the schools differ on how those facts are to be interpreted. I have little hesitation in saying that the greatest pitfall into which the analyst is likely to fall is the so-called "psychologist's fallacy"—namely, reading into a discovered experience his own thoughts and interpretations. The risk comes from the patient and from the analyst. The analyst may read into the patient's experiences his own interpretations and theories, but the patient himself may commit the psychologist's fallacy in ascribing to his own early experiences the interpretation of a later day.

Conclusions.

The foregoing considerations encourage us in the belief: (*a*) That it is possible to recover in memory experiences of infantile life—nor is there any reason why we should not. (*b*) That confirmation of these experiences can be found not only in objective verification, but in corroboration, and by the effects of the revival of these experiences. (*c*) That many of these early experiences, whilst themselves true, may become distorted by interpretations of a later time.

It is therefore only as we investigate, by direct observation and much more thoroughly than we have yet done, the actual behaviour of infants and children, that we shall be able to divest these memories of their accidental accretions and unfold the mind of a child as it really exists, a need of fundamental importance, whether from the point of view of psychopathology or of preventive mental hygiene.

"PORTIA" NON-FLAM. EYE SHADES.

WE have received from Messrs. Solport Brothers, Ltd., 184-190, Goswell-road, E.C. 1, specimens of their "Portia" Non-Flam. Eye Shades. These are made in three shapes—namely, for right eye, left eye, or either eye—from semi-opaque material, pink lined green, and also from green transparent material. The severe tests to which we have put the shades show that it is not strictly accurate to suggest that they are non-inflammable, but it is only under conditions not likely to occur normally that the material can be made to burn. The shades are certainly an improvement on those made from celluloid, both in utility and appearance.

DALRYMPLE HOUSE.

THE Forty-fourth Annual Report of Dalrymple House for Inebriates at Rickmansworth shows that Dr. F. S. D. Hogg's successful work is being maintained. Sixty-four patients were admitted during 1927, eleven of them under the Inebriates Act. All were alcoholics except for one morphine and two heroin addicts. Nearly all, including three sufferers from delirium tremens, made good recoveries. The average period of residence was seven to eight weeks for private patients and 23 to 24 weeks for those under the Act. The percentage of good results steadily increases in a ratio corresponding with the length of stay; this is, of course, partly due to the early discharge of patients unsuitable for treatment, but those who stay longest are often borderline, mentally deficient, and chronic cases for whom little can be hoped. Dr. Hogg points out that time is an essential factor in the treatment of any addiction and is closely associated with those elements of habit, self-suggestion, and self-education that play such an important part in the cure. The length of time that will strike the happy medium between staleness and discharge whilst still unstable must be a matter for careful individual consideration in every case. In an interesting statistical appendix Dr. Hogg gives particulars of discharged patients, relating to their age, previous residence, occupation, temperament, habits, and history. The report is illustrated with a number of photographs of the beautiful grounds.

THE SURGERY OF YESTERDAY AND TO-MORROW.

To the Editor of THE LANCET.

SIR,—As reported in THE LANCET of June 9th, p. 1207, the address of the President of the Royal College of Surgeons of England delivered at Addenbrooke's Hospital, Cambridge, savours somewhat of the utterance of the Pharisee who was not as other men. If the conditions prevailing in a Leeds operating theatre, 40 years ago, as described, were typical of English surgery generally they were bad. If not typical then Leeds must have been a curious centre.

My memory recalls the state of affairs in the Glasgow Western Infirmary, 50 years ago, soon after Lister left Glasgow, and while his teaching, and carbolic spray, were in the ascendant. Scrupulous cleanliness was then the order of the day, both with surgeons and dressers, supplemented but not replaced, by the all-penetrating spray. Coats or jackets, which may, or may not, have been stained were substituted for out-of-door "frocks," but they never appeared like the disreputable old coats gloated over by Leeds surgeons. There was almost an odour of sanctity in the theatre when the operating surgeon entered, looking like a bishop, with his working jacket protected by a white apron, and the jacket sleeves hidden by freshly laundered white sleeves, which closely gripped the arm just above the wrist and extended well over the elbow. This surgical equipment probably foreshadowed the later development of sterile overcoats, and may have been the outcome of Lister's influence. At any rate, Glasgow must have been years ahead of Leeds in the matter of its ablutionary technique. Bacteriology was then unknown, but *vis medicatrix naturæ*—the patient's power of resistance—was ever kept in view and wisely so.

I am, Sir, yours faithfully,

Scarborough, June 10th, 1928. JOHN IRVING.

To the Editor of THE LANCET.

SIR,—The following quotations may interest some of your readers:—

1. Erichsen, Science and Art of Surgery, tenth edition 1895 (seven years after the introduction of Lister's antiseptic surgery), p. 2. "When we reflect . . . we can scarcely doubt that the limits of surgery have been nearly reached . . . The surgeon of the future can scarcely hope to invent new operations; he must be content to modify and perfect those that have been devised by the genius and skill of his predecessors. . . . But if the mechanical art of surgery has attained to so high a degree of perfection that we can scarcely hope for much further progress in that direction, the case is widely different with the science."

2. Sir Berkeley Moynihan, at Cambridge, June 1st, 1928 (as reported in THE LANCET, June 9th): "The craft of surgery has to-day reached something near its goal. If operations have to be practised in the future, it is not possible to imagine any considerable improvement upon the methods and results of to-day, as exemplified in the hands of the great masters. . . . The art of surgery has outrun its science."

I am, Sir, yours faithfully,

London, W., June 11th. A. S. BLUNDELL BANKART.

NATIONAL COUNCIL FOR MENTAL HYGIENE.—A public meeting of the Council will be held on Thursday, June 21st, at 5 P.M., in the Council Chamber, Birmingham. Addresses will be given by Sir Maurice Craig and Dr. Crichton Miller on the Prevention of Nervous Breakdown.

BRITISH HOSPITALS' ASSOCIATION.—The eighteenth annual meeting and conference of the Association will be held at Southport on Thursday and Friday, June 21st and 22nd, under the presidency of Sir Arthur Stanley. On Thursday morning Sir Thomas Horder will read a paper on the Place of the Voluntary Hospitals in Relation to Health Services, and in the afternoon Mr. G. Q. Roberts, secretary and receiver of St. Thomas's Hospital, will speak on Problems of the Voluntary Hospital of to-day compared with Problems of the Past. A discussion on the Place of the Nurse in the Hospital will be opened on Friday morning by Miss M. E. Sparshott, and in the afternoon visits will be paid to hospitals and other institutions. The conference secretary is Mr. J. H. Shaw, Southport General Infirmary, Pilkington-rd., Southport.

Croonian Lectures

ON THE

INTERPRETATION OF GASTRIC SYMPTOMS.

Delivered before the Royal College of Physicians of London

BY CHARLES BOLTON, C.B.E., M.D., D.SC. LOND., F.R.C.P. LOND., F.R.S.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE III.*

(Delivered on June 12th.)

I HAVE classified the symptoms of functional disorder of the stomach into three fundamental groups or syndromes and connected each group with a different part of the gastric mechanism. I shall now consider what alterations in this mechanism are responsible for the production of these symptom groups and what are the causes of these alterations.

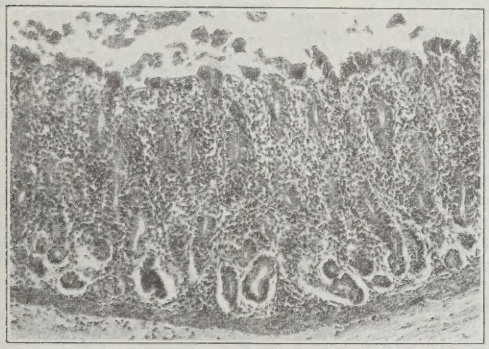
A. PYLORIC SYNDROME.

The changes producing this group of symptoms are due to irritability of the pyloric sphincter which produces its effects in the later stages of digestion when the stomach is partially empty and its contents are most irritating. The normal relaxation of the sphincter is interfered with and ultimately it becomes spasmodic, the spasm involving the pyloric vestibule or only the end of it; its two functions whereby it acts as regulator of the output of food and of the acidity of the gastric contents are upset, so that delayed emptying of the stomach and hyperacidity of its contents result.

Causes.

1. *Indigestible and Irritating Food.*—The normal movements of the pyloric sphincter are effected by local reflexes through the myenteric plexus. It is

FIG. 1.



Section of monkey's stomach showing gastritis. There is round-celled infiltration of the mucosa and destruction of the gastric glands (HCl experiments).

not thoroughly understood how this is accomplished. The character of the food is probably one of the chief factors, for the pylorus has undoubtedly a selective action. It separates the fluids from the solids and holds up those portions which require further disintegration. The constant ingestion of food difficult to disintegrate, particularly if bolted and containing irritants, leads to deficient relaxation of the pylorus through excessive irritability, which, once established, tends to persist.

2. *Hyperacidity of the gastric contents* resulting from this pyloric hypertension or hypersecretion increases and maintains the pyloric irritability and finally produces spasm, for Cannon [1] has shown that the HCl of the gastric juice is at all events a factor in the control of the pylorus, so that there can be no doubt that the myenteric reflex responsible for this control is very sensitive to HCl, and in the presence of an excess produces pyloric spasm when it is irritable.

3. The facility with which these effects are produced depends upon the condition of the nervous system as regards stability. There are three conditions which tend to render unstable the reflex mechanism controlling the pylorus.

FIG. 2.

Section of monkey's stomach showing an enlarged follicle bursting on the surface and forming a follicular ulcer (HCl experiment).

(*a*) A direct effect upon the *myenteric plexus* itself. This effect is produced by a *chronic ulcer* situated in the pyloric vestibule, especially if near the pylorus, or a duodenal ulcer. An acute ulcer, although there may be nerves exposed in its base, produces no characteristic symptoms; it is the chronic ulcer which acts as a focus of irritation to the part of the stomach in which it is situated. The wall of the moderately stretched stomach is only about 4 mm. thick, and it is therefore rapidly destroyed during the formation of an ulcer. The muscular coat retracts in all directions and the base of the ulcer is formed of newly formed fibrous tissue or some adjacent organ. There are no nerves in this base to be irritated by the gastric contents except such extrinsic nerves as may by chance be caught up outside the stomach. The fibrous base of the ulcer extends in all directions into the surrounding wall of the stomach between and involving its coats by a slowly progressive type of chronic inflammation; it gradually infiltrates the myenteric plexus and the endings of the extrinsic nerves, and it is only reasonable to assume that it acts as a focus of irritation to the plexus, whose function is to coördinate the movements of the different parts of the stomach. It is not common for a *cancer of the pylorus* to produce this effect, although now and again such an event occurs.

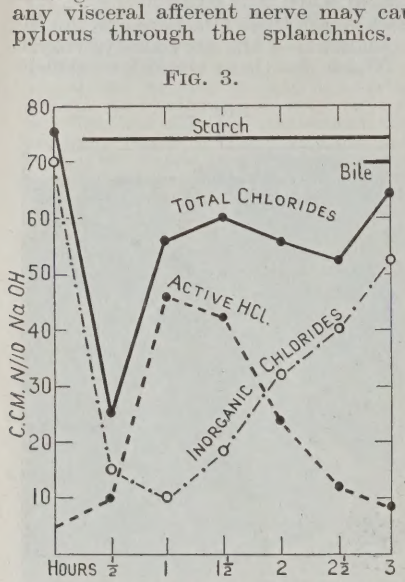
Pyloric gastritis is held by Faber, of Copenhagen,[2] to be a cause of pyloric symptoms, because he has found this condition in the resected parts of patients who have been operated on for supposed ulcer, and who showed pyloric symptoms. He is doubtful, however, how often hyperchlorhydria can be referred to gastritis. Gastritis in this position is common enough, and I suggest that it may be a secondary result of the hyperchlorhydria. In 1915 [3] I was able to produce gastritis and follicular ulcers by feeding monkeys daily with HCl solutions of 0·28 per cent. and upwards (Figs. 1 and 2). In no case did the ulcers show any tendency to extend or become chronic. So that the primary event may be pyloric irritability or hypersecretion, and the secondary results hyperchlorhydria and gastritis.

(*b*) The second condition which renders the pyloric mechanism unstable is *reflex irritation*. According to Cannon's [1] experiments of intestinal section and irritation of the colon pyloric hypertension should result from disease of the bowel as a reflex effect. Moynihan [4] first described pyloric spasm, that is to

* Lectures I. and II. appeared in THE LANCET of June 9th and 16th respectively.

say of the sphincter, and also the pyloric vestibule, as being secondary to appendicitis, and Cole [5] and Barclay [6] were early X ray observers who noted the same condition as the result of various conditions in different parts of the bowel by the X rays. Since this time numerous later observers have described similar findings. Carlson and Litt [7] find that stimulation of any visceral afferent nerve may cause spasm of the pylorus through the splanchnics. In the present state of our knowledge regarding this difficult subject we must conclude that reflex irritation from some other part of the alimentary system is a cause of pyloric irritability.

FIG. 3.



Normal curve of total chloride, inorganic chloride, and active hydrochloric acid.

(*c*) Finally, any condition rendering the *central nervous system unstable* is a factor in contributing to produce pyloric irritability. The effects of neurasthenia and other forms of nervous disorder, however, are much less marked upon the pyloric sphincter than upon the body of the stomach, and are not so often a primary cause of the disturbance, although once established they no doubt perpetuate it.

Effects Produced.

Whatever is the primary cause of the pyloric irritability is a matter of little moment; the effects produced are the same in each case.

1. The pylorus is first interfered with in its capacity as *regulator of the output of food.* When the stomach is filled with food the pylorus assumes its condition of postural contraction, whereby it locks the food in the stomach and yet there is no increase in the contraction tension of its muscle fibres. Expulsive peristalsis begins at once about the middle of the stomach and from this point waves pass over the pyloric portion without ceasing, and increase in vigour as the stomach empties. These waves deepen towards their termination, a constant central stream of gastric contents flowing backwards, and the deeper the waves the more forcible the velocity of this backward current. The pyloric sphincter in its state of postural tonus determines the rate at which food leaves the stomach. It does not relax before every peristaltic wave, neither does it always relax to an equal degree. At the beginning of digestion it relaxes just enough to allow liquids and finely divided solids to pass out, pieces of food difficult to disintegrate, hard masses, and irritant material are shot back into the pyloric vestibule to undergo further softening and subdivision. In this way the pylorus exhibits its function of selecting properly prepared food—namely, that in solution, finely emulsified and disintegrated, and partially digested to be passed on to the intestines. The different foodstuffs leave the stomach at different rates. The pylorus may hold up indigestible material for a considerable time, because it is a common experience for patients to complain that they have vomited easily recognisable articles 24 or more hours after ingestion, although they have eaten other food in the meanwhile which has passed out of the stomach; or such indigestible residue may be washed out after everything else has left the stomach

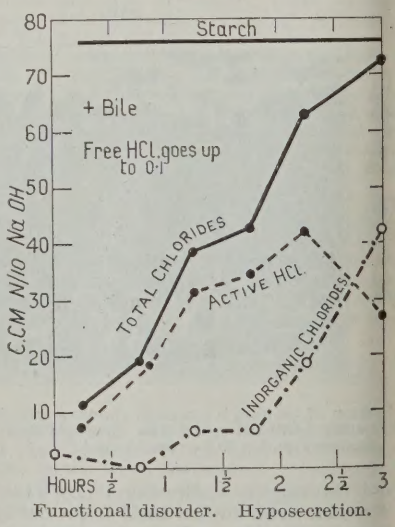
The gastric contents thus become more irritating as digestion proceeds, because the soluble and easily disintegrated food has passed out of the stomach, leaving the more irritating portions behind mixed with gastric juice. If food difficult of disintegration or irritating is eaten the factors tending to bring about pyloric relaxation become less effective as digestion proceeds; the pylorus refuses to relax and finally becomes spasmodic. Whether the pylorus is initially irritable or becomes so as the result of irritating food during digestion makes no difference. The result is the same. Peristalsis increases in vigour as in the case of all opposed muscles, and the tonic contractions of the body become more pronounced, so that the internal pressure is raised, and finally the pyloric vestibule becomes spasmodic with the sphincter.

If the stomach has emptied rapidly at the beginning, so that when pyloric spasm comes on very little is left in it, these exaggerated movements of the body are of precisely the same nature as the normal hunger contractions of the empty stomach, and the pain experienced owing to the pyloric spasm becomes blended with an empty, hungry sensation. If the gastric contents are of considerable volume when the spasm occurs the feeling is one of fullness. In either case referred pain may or may not appear in the region representing the body. As the cardiac sphincter relaxes from time to time regurgitation of the acid contents occurs into the œsophagus; this is more likely to appear if the volume of the gastric contents is considerable, or if its occurrence is favoured by the position of the patient, or the intra-abdominal pressure. The usual result is that the fluid causes a burning sensation in the throat, is re-swallowed, and a few deglutition movements clear the œsophagus; or the fluid if it reaches the mouth is spat out.

The further changes in the œsophagus will be described later, but marked œsophageal symptoms or wind eructations are by no means very common in the pyloric syndrome as the patients have not as a rule any special neuropathic tendency. When food is eaten the symptoms are put an end to because the muscular movements producing them are stopped, as I have described in the last lecture, and the cause is removed — that is to say, the acid contents of the stomach are diluted and neutralised.

It was demonstrated by Carlson [8] that the hunger contractions of the empty stomach are inhibited by the introduction of food, the organ assuming its condition of postural contraction. Moreover the chewing and swallowing of food may also inhibit them. It is a well-known fact that immediate relief by food is best obtained in those cases of pain with hunger which occur when the stomach is relatively empty and also that quite a small amount of food, such as a biscuit, will relieve; in these cases also relief by alkalis is more complete. These two facts receive this explanation, in that inhibition is more effective when the stomach is almost empty, for the later the symptoms commence the less irritable is the stomach and the more easy to relax, and neutralisation of more importance since the HCl is an important factor in causing the spasm. Œsophageal symptoms in such

FIG. 4.

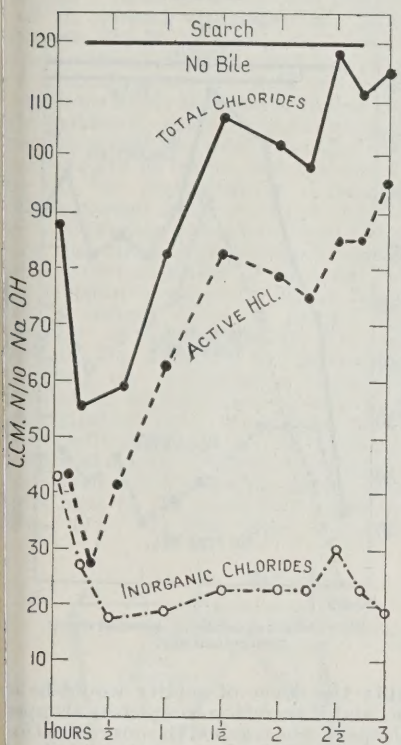


Functional disorder. Hyposecretion.

cases can usually be easily overcome by washing the œsophagus by swallowing water.

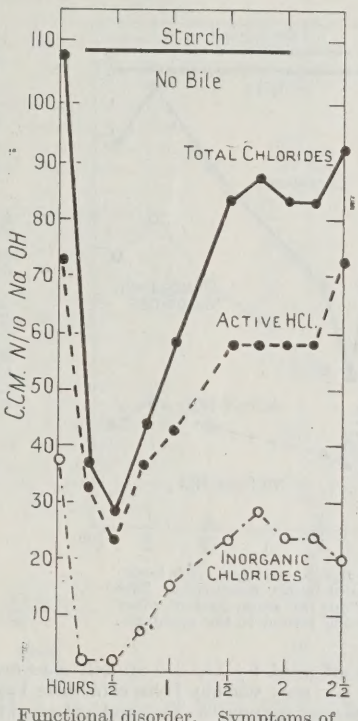
It is easy to understand the relaxation of the body and pyloric vestibule, but one difficulty presents itself, and that is why the pyloric sphincter itself is relaxed by food. If entirely dependent upon the acidity it will relax when this is neutralised, but it is probable that the sympathetic, which relaxes the stomach and closes the sphincter, is able to induce in the latter the through the myenteric plexus or vagus; and Carlson[7] has shown that pyloric spasm may be reduced by stimulation of the sympathetic. When the extrinsic nerves are the original cause of the irritability similar effects must be seen in a more irregular and complicated fashion. It is not so common for pyloric irritability to be directly due to instability of the central nervous system, but as a reflex effect through the sympathetic from other portions of the alimentary

FIG. 5.



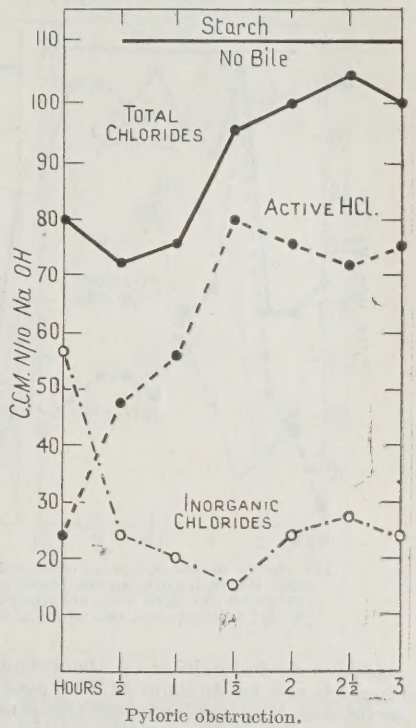
Duodenal ulcer.

FIG. 6.



Functional disorder. Symptoms of hyperchlorhydria.

FIG. 7.



Pyloric obstruction.

ondition of postural tonus when it is spasmodic. We o not really understand the precise action of the xtrinsic nerves of the stomach. The vagus is the notor and the sympathetic the inhibitory nerve; ut either will produce spasm or relaxation of either phincter. The result depends upon the strength of timulation and the stage of digestion, or the condition f muscular contraction at the time. If spasmodic a phincter will be relaxed, if relaxed it will contract Carlson). As the stomach is filled the vagus relaxes he cardia and body of the stomach during swallowing od so that pain is rarely experienced during the neal; during the emptying it increases the tone and eristaltic contractions of the stomach and tends to elax the pylorus, thereby increasing the emptying fficiency[9]; excessive stimulation causes spasm of ne pyloric and relaxation of the cardiac end.

So that in this condition of pyloric irritability due o improper food or local irritation as in duodenal lcer and starting as an excess of the local pyloric eflex through the myenteric plexus, the vagus reflex no doubt in many cases unduly excited and called to aid in the increased peristalsis and tone of the omach, but when excessively stimulated it induces, at all events increases, the pyloric spasm—that is say, of the sphincter and vestibule. In favour of is view is the early rapid emptying of many of ese stomachs, the hypersecretion which is not ncommon, and the effect of atropine in often relaxing ne sphincter. The action of the sympathetic, when od is eaten, is to inhibit these effects more or less ccessfully and to reduce the pyloric spasm to the ndition of postural tonus when it is due to overaction canal it is, as we have seen, common enough. In such a case relaxation of the sphincter by the sympathetic cannot be expected so that the symptoms would not be so well relieved by food, and in his original description of this reflex dyspepsia Moynihan points out that the gastric pain in this condition differs from that of gastric ulcer in not appearing so regularly at a fixed time after food and having no fixed interval of relief after a meal.

The final stage of this interference with pyloric action, which is seen on occasion, is one in which muscular insufficiency appears and the stomach shows slight dilatation. This condition, which may be recognised now and again by the X rays, is easily recovered from and causes little alteration in the symptoms. All the muscular disorders described above may be seen on occasion by the X rays, but a series of cases cannot be followed through from beginning to end, otherwise our difficulties would be at an end.

2. The next function of the pylorus to be interfered with is that of *regulator of the acidity of the gastric contents*. It accomplishes this by relaxing and permitting the regurgitation of alkaline duodenal contents into the stomach at a certain stage of digestion. As this process has recently been denied I must give a brief description of the foundations upon which it is based, and point out how its opponents have fallen into error.

The first observer to recognise bile in the stomach was Beaumont,[10] but no significance was attached to its presence till Boldyreff's experiments[11] clearly established the fact and demonstrated the importance

of regurgitation of pancreatic and intestinal juices and bile into the stomach. He showed this spontaneous regurgitation into the empty stomach of both the dog and man; also that regurgitation occurred when fats were introduced into the stomach by mouth or through a gastric fistula; and that regurgitation of these juices was brought about when large quantities of HCl or other acids were introduced into the fasting or digesting stomach. He proved conclusively that the introduced acid was neutralised by the pancreatic juice regurgitated, showing that the reduction of acidity was due neither to absorption of acid by the stomach nor to dilution of the acid by any watery secretion. He considered that this process of regurgitation neutralised the acidity of the gastric contents down to 0·15 per cent. to secure the optimum acidity for digestion by pepsin and to protect the intestine. He styled the process the "self regulation of the acidity of the gastric contents."

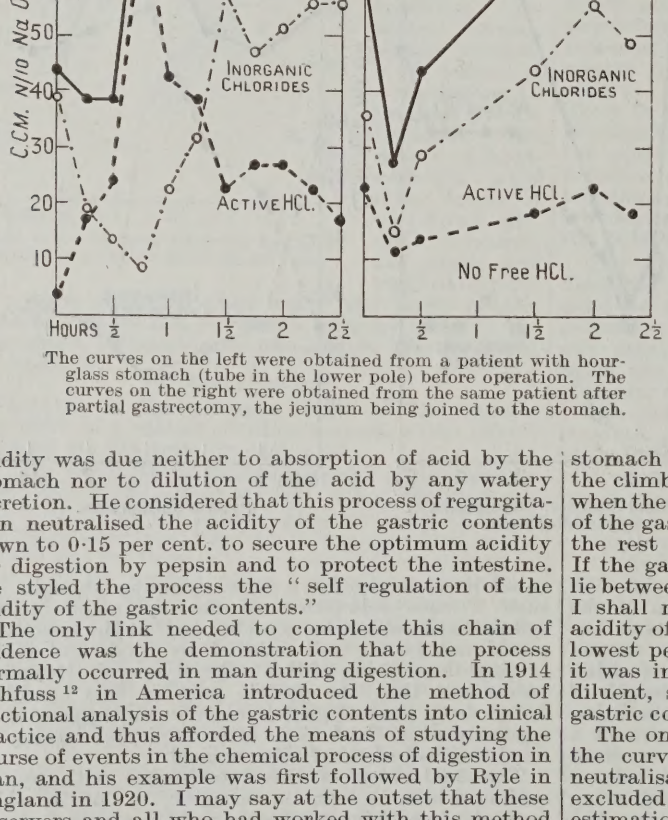
The only link needed to complete this chain of evidence was the demonstration that the process normally occurred in man during digestion. In 1914 Rehfuss [12] in America introduced the method of fractional analysis of the gastric contents into clinical practice and thus afforded the means of studying the course of events in the chemical process of digestion in man, and his example was first followed by Ryle in England in 1920. I may say at the outset that these observers and all who had worked with this method recognised the principle enunciated by Boldyreff of duodenal regurgitation. For example, in 1916 Spencer, Myer, Rehfuss, and Hawk [13] confirmed Boldyreff's findings of trypsin in the stomach, and in 1921 Rehfuss and Hawk [14] stated that during gastric digestion the pylorus shows heightened tonus with but little regurgitation, except that which is essential to maintain optimum acidity in the stomach, but that during the resting phase the pylorus relaxes, permitting a ready reflex of alkaline duodenal secretion. In the same year Bennett and Ryle [15] also subscribed to this theory of duodenal regurgitation, and concluded that the acidity of the gastric contents depends upon the balance between acid and alkali. Now according to the teaching of Rehfuss, the curves of free HCl and total acidity represented the course of gastric secretion. Isosecretory curves were those whose peak rose to a maximum of about 0·2 per cent. and comprised, according to Bennett and Ryle, about 91 per cent. of the total; hypersecretory and hyposecretory curves those which reached higher than or failed to reach the isosecretory level; if the curve did not descend or continue to rise, so that its highest point was reached when the stomach was empty, it was styled by Bennett and Ryle the "climbing type" of curve and occurred in about 5 per cent. of healthy people.

In 1921 Goodhart and myself [16] commenced the study of these curves. Our argument was that the curve of acidity of the gastric contents could not possibly mean the same thing as the curve of secretion. If secretion continued at the same strength till the stomach was empty the curve of acidity would be of the climbing type, and if secretion completely stopped when the top of the peak was reached the concentration of the gastric contents would remain at that level and the rest of the curve would draw a horizontal line. If the gastric juice fell off in acidity the curve would lie between these two levels. Rosemann, to whose work I shall refer later, had shown that such a fall in acidity of the gastric juice did actually occur; but the lowest percentage of HCl reached was 0·319, so that it was impossible for the gastric juice to act as a diluent, since the average height of acidity of the gastric contents was in the region of 0·2 per cent. HCl.

The only other condition which would bring down the curve of acidity of the gastric contents was neutralisation, for absorption of acid had been excluded as the cause. We made complete chloride estimations every quarter of an hour and found that as the acid curve went up that of neutral chloride remained low, and as the percentage of acid fell that of neutral chloride increased pari passu, the total chloride curve remaining unaffected (Fig. 3). It was also found that in cases of diminished secretion the total chloride curve was low (Fig. 4). We concluded that the real secretory curve was not the acid curve as described, but followed that of the total chlorides, and that the acid curve represented the progress of the neutralisation process only, which in its turn entirely depended upon relaxation of the pyloric sphincter at a certain stage of digestion, permitting of duodenal regurgitation.

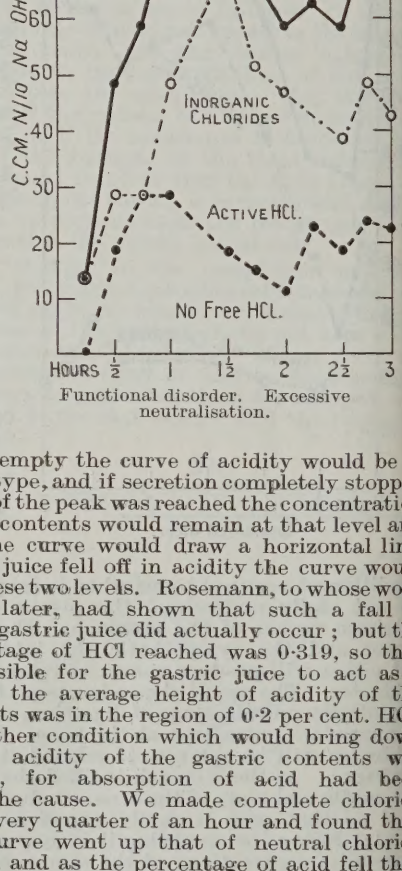
These results have been confirmed by Apperly,[17] by Baird, Campbell, and Hern [18] and by Roberts.[19] We have formed the definite hypothesis that in the condition of pyloric irritability the pylorus refuses to relax as described above at the usual time and the wave of neutralisation fails to appear. The further course of the curve depends upon the secretory

FIG. 8.



The curves on the left were obtained from a patient with hour-glass stomach (tube in the lower pole) before operation. The curves on the right were obtained from the same patient after partial gastrectomy, the jejunum being joined to the stomach.

FIG. 9.

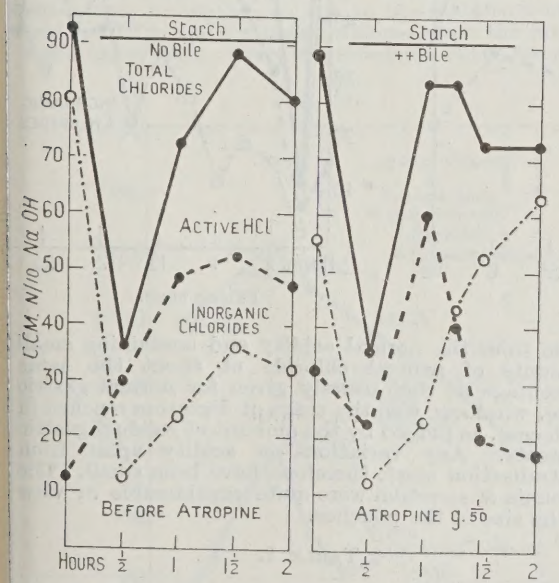


Functional disorder. Excessive neutralisation.

activity of the stomach and the behaviour of the pylorus. The acid curve may continue to rise as in the climbing type; or it may draw a horizontal line; or the pylorus may relax occasionally to different degrees and the acid curve fall with each relaxation to rise again as the pylorus tightens up. This in our opinion is the condition described as hyperchlorhydria or acid dyspepsia (Figs. 5 and 6).

We regard the following facts as being confirmatory of the conclusion at which we have arrived. (1) Bile appears in the stomach from the beginning in cases of excessive neutralisation, and frequently towards the end in normal neutralisation, although it is often absent. (2) In inorganic obstruction of the pylorus when regurgitation does not occur there is no evidence of neutralisation, the acid curve does not fall, but continues in its horizontal course (Fig. 7). (3) When the pylorus is cut out or gastro-enterostomy performed in such a case the total chloride curve remains of the same height as before, but achlorhydria is established by the free regurgitation of intestinal contents and bile is present in the stomach (Fig. 8). (4) In certain normal persons owing to excessive duodenal regurgitation the same condition of achlorhydria is established, with a normal height of the total chloride curve, and the constant presence of bile in the stomach (Fig. 9). (5) In certain cases of pyloric hypertension with absence of neutralisation the administration of atropine in addition to diminishing the secretion converts the climbing or horizontal curve into a normal one by dilating the pylorus and allowing a free regurgitation from the duodenum (Fig. 10). (6) In the condition of recovery from an attack of dyspepsia a normal curve obtained by the gruel meal may be converted into a climbing one by adding badly cooked split peas to the meal and so irritating the pylorus (Fig. 11). (7) The rapid ups and downs which

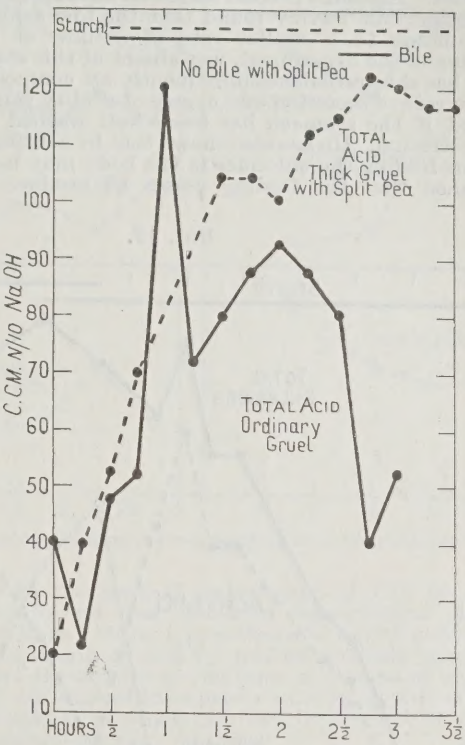
FIG. 10.



Curves obtained before and after administration of atropine.

sometimes occur in the curve can only be explained by the vagaries of a sphincter muscle (Figs. 12 and 13). In our original paper dealing with duodenal regurgitation we stated that the curve of gastric secretion followed the course of the total chlorides, but did not assume that the percentages of Cl in the two were identical. The reason for this was that we realised that the HCl of the gastric juice might not account for the whole of the total chlorides present, because no exact data were available as to the amount of Cl in each of the other secretions. Hansman, Day, and Clifton [20] in a recent paper have calculated that the total amount of Cl present in the gastric contents is at times greater than can be accounted for by the Cl in the gastric juice, assuming that there are present certain proportions of mixed secretions each of known Cl percentage, and that the Cl secreted by the stomach is always in the form of acid. They have concluded that the stomach allows the passage of chlorides through the mucous membrane, and that

FIG. 11.



Curves showing amount of acid in gastric contents after a meal of (*a*) ordinary gruel, and (*b*) gruel thickened with split pea. The split pea has converted the curve into a climbing curve, prolonged the emptying time, and prevented regurgitation of bile.

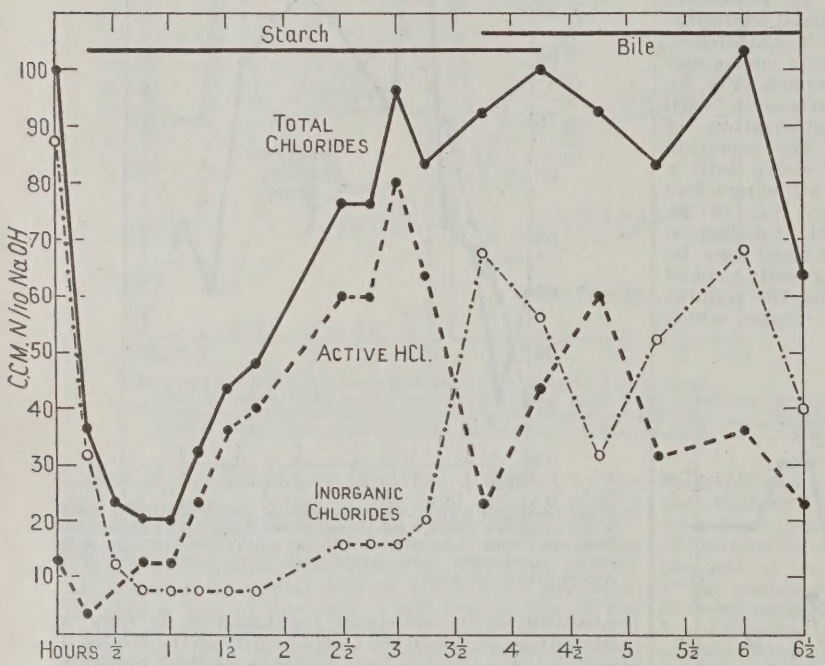
neutralisation by duodenal regurgitation is only a contributory factor to the fall of acidity as the stomach empties. The gastric cell receives neutral chloride from the blood and transforms it into HCl, so that there can be little doubt that neutral chloride at times escapes this transformation in certain pathological conditions, but the hypothesis that this escape normally occurs at a stated time as a purposive act to reduce the amount of HCl by neutral chloride is certainly not justified, especially since the data upon which they rely are uncertain. Apperly [21] has, moreover, found that the chloride strength of the duodenal fluids may be enough to account for these chloride variations without invoking the aid of the passage of neutral chloride through the stomach wall, which idea he dismisses. This is borne out by Baird, Campbell, and Hern.[18] Roberts,[22] from observations upon the fasting juice, finds that the hypothesis of secretion of neutral chloride best explains his results, but admits that this explanation is only tentative owing to the number of uncontrollable factors present. It is true that the gastric juice obtained from the Pavlov fistula fluctuates in its degree of acidity, and Pavlov [23] himself has definitely proved that this fluctuation depends upon the rate of flow of the gastric juice, and the time it remains in the pouch; and that the cause of the low acidity is due to neutralisation when small amounts are secreted. The neutraliser is the alkaline mucus coating the surface of the mucous membrane, so that at the beginning of secretion the small amounts of juice trickling from the gastric tubes are neutralised,

but this neutralisation process soon ceases to produce an effect as the secretion is fully established.

There can be no doubt that Pavlov is correct in his statement that the greater the quantity of juice the more rapidly will it flow over the stomach wall, and the less will it become neutralised, so that in the use of the Pavlov pouch allowance must be made for such variations in the acidity of the gastric juice when small amounts are secreted, because it has neutralising properties. The same process occurs on the subsidence of secretion, but Pavlov found that the low acidity, corresponding to a similar rate of outflow at the beginning of the experiment, was absent at this stage, and he has shown that not infrequently all connexion between rate of secretion and degree of acidity can be removed if the stomach has been well washed by ample secretion. He has also shown that by continued fictitious feeding the chlorides in the body may be so diminished that the feeding ceases to produce an secretion of a dilute gastric juice of a constant acidity of 0·18 per cent. After the first hour the acidity percentage fell to 0·146, but even after seven hours it remained at 0·109. The acidity therefore fell somewhat as secretion proceeded.

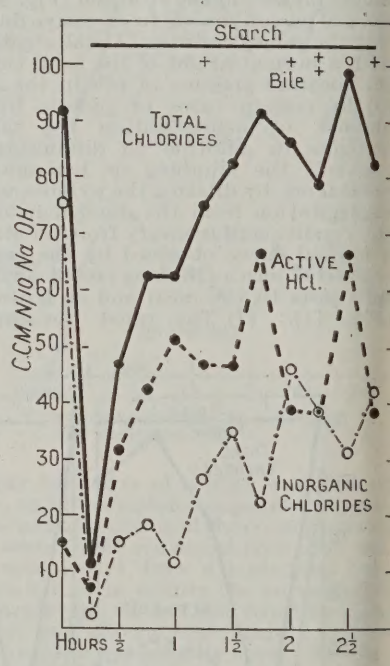
In 1921, at the commencement of our work with the fractional test-meal at University College Hospital, E. K. Martin and myself did some fistula work on cats. The idea was to collect the juice in fractions from the fistula whilst a fractional test-meal was in progress. We found that this was impracticable, because with the fluid meal we administered, although secretion might begin in fair amount, at the end of about an hour or a little more it sank to driblets of fluid and mucus. We therefore collected the juice from the beginning to the end of each experiment. I quote five experiments (Table I.). The figures show the average percentage composition of the juice collected over each period of time. They all show a gastric juice varying

FIG. 12.



Functional disorder.

FIG. 13.



Pyloric ulcer.

effect; and yet the fluctuations of acidity in the samples of juice last secreted lie within normal limits. Although neutralisation is an important cause of fluctuations in the acidity of the gastric juice, at the same time Pavlov recognised the possibility of some other relation existing between the rate of secretion and the degree of acidity. With this idea in mind Rosemann,[24] in 1907, advanced the hypothesis that the amount of HCl, which the gastric cell forms from the total chloride supplied to it, depends upon its secretory energy, so that when this energy diminishes towards the end of secretion the HCl content of the gastric juice falls and the neutral chloride rises, so that the total chloride remains more or less constant. He did a large number of experiments with gastric fistulæ using the whole stomach and employing the method of sham feeding, the juice being collected every half hour. In no case did the acidity fall below 0·319 per cent., and it was usually not less than 0·45 per cent. after four or five hours. The greatest rise in neutral chloride was 0·22 per cent. These variations are very small, and may be described as being almost within normal limits as Pavlov described. In 1915,[3] whilst studying the action of free HCl upon the connective tissue base of experimental gastric ulcer, I had occasion to use pilocarpine and did six acute experiments. I found that it produced a little from the normal acidity and containing small amounts of neutral chloride of about the same percentage as that usually given for normal gastric juice, whatever was the stage of digestion reached in each case, as judged by the amount of residual gastric contents. Any variations in acidity apart from neutralisation must, therefore, have been small. The amounts of secretion were quite considerable in view of the size of the pouches.

TABLE I.

Cat.	Meal.		Pavlov fistula.				Stomach contents.

E	Meat	?	1¼	5·05	0·556	0·092	?	0·093	0·115

It seems quite likely that there are two factors influencing the acidity of the gastric juice: (1) neutralisation at the beginning and end of secretion,

and (2) diminished formation of HCl after a time owing to lessened energy of secretion. The alterations in acidity are related to the rate of flow of the gastric juice, so that in all Pavlov experiments the amounts of juice secreted should be recorded. Such alterations vary from animal to animal, and in the majority of cases are not large, and occur at the beginning and toward the end of secretion. Within the last few weeks MacLean [25] has published two papers upon this subject. He has produced Pavlov fistulæ in two dogs and collected the juice from them every half hour during digestion. He shows two curves of acidity. He has obtained a juice containing a constant percentage of total chloride throughout the experiment, so that as the percentage acidity rises to its maximum that of the neutral chloride falls, and as the secretion subsides the fall in acidity is accompanied by a rise in neutral chloride percentage. At the beginning and end of secretion there are only very small quantities of juice, so that an analysis cannot be made, and he assumes that at these periods the secreted juice consists of sodium chloride almost entirely. The important difference between his observations and those of others is that the fall in acidity he obtains as the secretion subsides is greater, so that at the end of three hours the percentage acidity stands in the region of 0·2. His explanation is that during the rise of secretion the sodium chloride changes into HCl, and during its subsidence this process gradually ceases so that the HCl is replaced by neutral chloride. This subsidence he regards as due to the inhibitory effect which HCl in the stomach produces upon the further secretion of HCl. There is no mention of the amounts

FIG. 14.

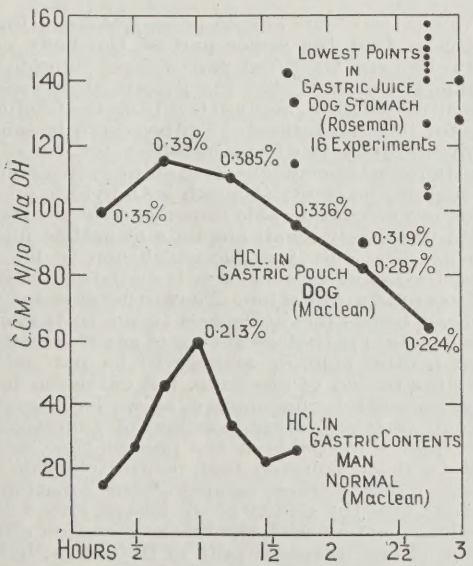

Chart comparing percentage of hydrochloric acid in (1) gastric contents after test-meal in man; (2) gastric juice from a Pavlov pouch in the dog; and (3) gastric juice from the whole stomach of the dog after a sham feed.

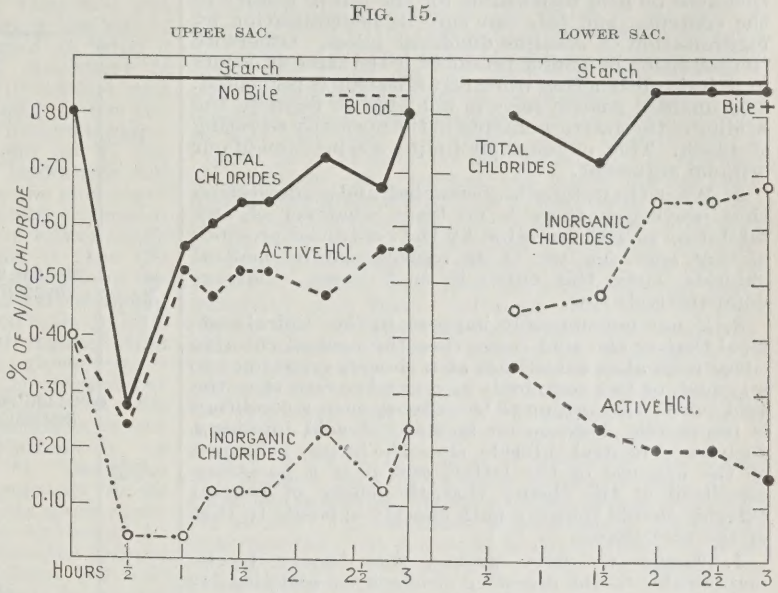
secreted nor of neutralisation by mucus at any stage of secretion and however small an amount of juice is secreted. This explanation of the process of gastric secretion cannot, therefore, be accepted as it stands without further investigation.

As regards the entirely *separate question of the acidity of the gastric contents*, MacLean regards the curves of this acidity as being produced by the same process as the secretory curves of gastric juice he gives. He considers that the reduction in acidity obtained by the fractional test-meal in the digesting stomach is due to the gradual replacement of HCl by neutral chloride and that duodenal regurgitation plays no part in it. Such a hypothesis is unlikely, because a replacement of acid by neutral chloride would only affect the acidity of the juice in process of secretion, and not that of the already existing gastric contents, the acidity of which can only be lowered by dilution or neutralisation.

FIG. 15.



Simultaneous curves obtained from the two portions of an hour-glass stomach.

1. The acid curve of the pouch is of the same shape as that obtained by the clinical test-meal, but it does not follow that they bear the same interpretation; on the contrary, it is clear that they must represent different processes since the conditions in each are different. The acid curve of gastric juice draining out of the empty stomach cannot mean the same as the acid curve of the contents of the digesting stomach. At the height of the acid curve in the digesting stomach when the fall is about to commence there is present a variable amount of gastric contents of an acidity of, say, 0·2, which will gradually leave the stomach in the next one or two hours or less. *If duodenal regurgitation be excluded* the only fluid mixing with the contents during this time is the gastric juice which is being secreted. The composition of this juice during the various half hours of digestion according to MacLean is as shown in Table II.

TABLE II.

Time after meal.	HCl.	NaCl.	Time after meal.	HCl.	NaCl.
½ hour	0·35	0·18	2 hours	0·34	0·19
1 ,, ...	0·39	0·13	2½ ,, ...	0·28	0·25
1½ ,, ...	0·38	0·14	3 ,, ...	0·22	0·28

At this stage of digestion very small amounts of gastric juice secreted.

Fig. 14 shows the acidity of the same gastric juice plotted out as a curve, below which is the curve of acidity of the gastric contents of a normal person; the dots represent the lowest points of gastric juice acidity in 16 experiments by Rosemann. It is clear that admixture of this juice with the gastric contents cannot result in any fall of acidity in the contents,

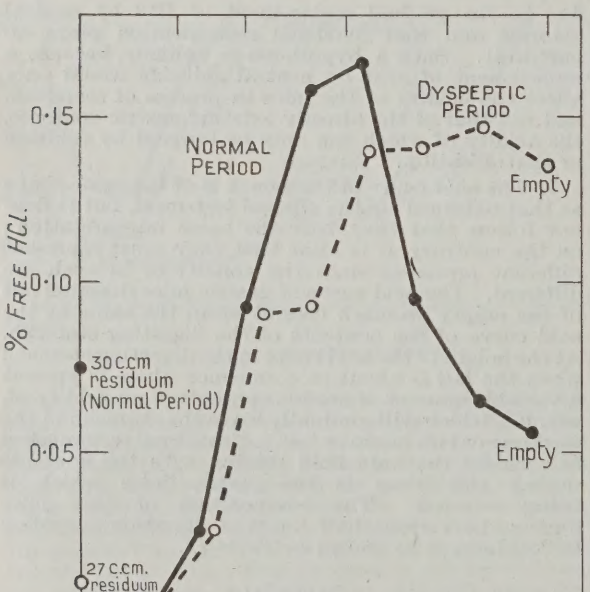
since the juice acidity is higher than the contents acidity all the time. Gastric juice, therefore, although it may contain an excess of neutral chloride, is unable to reduce the acidity of the gastric contents into which it is secreted, because its acidity is at all times greater than the contents acidity. Some other factor must therefore be held responsible for the fall in acidity of the contents, and this can only be neutralisation by regurgitation of alkaline duodenal juices. Otherwise the condition of acidity produced is the same as occurs in pyloric obstruction when regurgitation is prevented. The unaided gastric juice is not able to regulate the acidity of the gastric contents in the normally secreting stomach. This, of course, is simply a repetition of our original argument.

2. When the pylorus is obstructed, and regurgitation thus prevented, there is no trace whatever of any inhibition of HCl secretion by the continued presence of that acid, nor yet of its replacement by neutral chloride, since this curve in such cases is always comparatively low.

3. It not uncommonly happens in the clinical test-meal that as the acid curve rises the neutral chloride curve rises also, sometimes at a slower, sometimes at an equal, or less commonly at a quicker rate than the acid curve. According to this theory such a condition is impossible, because an increase of acid implies a decrease of neutral chloride, since the former is formed at the expense of the latter, and it is a necessary condition of the theory that the curve of neutral chloride should follow a path exactly opposite to that of the acid curve.

4. Finally we have proved this theory to be inapplicable to the digesting stomach by selecting for

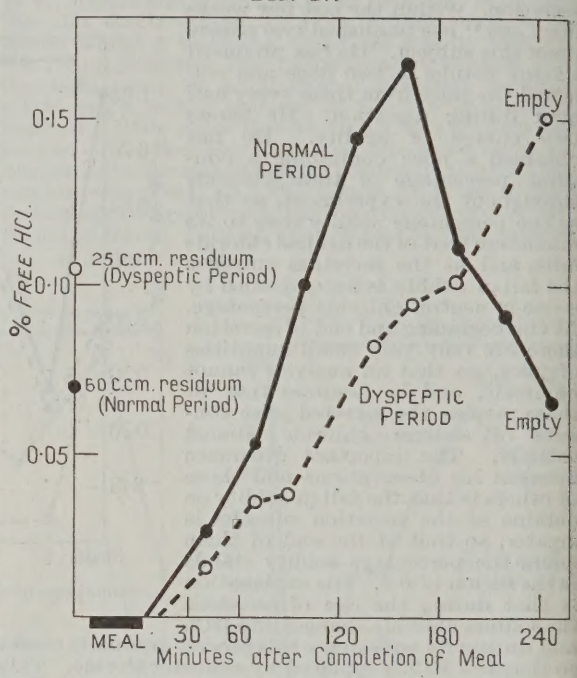
FIG. 16.



Hydrogen-ion concentration of gastric contents during digestion of test-meal (2 oz. oatmeal boiled in 1 pint of water) determined by quinhydrone electrode on samples of 1 c.cm.

observation an hour-glass stomach in which the constriction was situated about the middle of the body, so that there was ample secretion of normal acid gastric juice into both sacs. Two tubes were passed into the stomach under the X rays, one into the upper and one into the lower sac. From the upper sac we have obtained a curve of continuously high acidity with the very slight increase of 0·07 per cent. in the neutral chloride towards the end, and from the lower sac a curve of normal neutralisation. The tube in the lower sac did not work well at the beginning and an insufficient amount was extracted for reliable analysis, but the reaction of the fluid obtained was strongly acid. The fasting juice in the upper sac shows that some

FIG. 17.



Hydrogen-ion concentration of gastric contents during digestion of ordinary meal (chop 10 oz., including bone, potatoes 3 oz., tomato one, butter ½ oz., bread 3 oz., and water ½ pint) determined by quinhydrone electrode on samples of 1 c.cm. Note that the scale of the abscissa (time) is half that of Fig. 16.

neutralisation occurs in it in process of time (Fig. 15). It is clear that the upper part of the body cannot secrete HCl and the lower part neutral chloride; and it cannot be argued that the pyloric glands secreted the neutral chloride, because it is from the fundus that a Pavlov pouch is formed. Neither can it be said that the pyloric juice was the neutraliser, for it is of little importance in the neutralisation of the gastric contents, although in the empty stomach both pyloric juice and mucus are of considerable importance as neutralising agents when only small amounts of gastric juice are present. The only possible conclusion to be drawn is that the fall in the acid curve is due to neutralisation by duodenal regurgitation. The further evidence which MacLean brings forward seems to me to throw light upon a certain pathological type of gastric secretion in which neutral chloride appears to be put out from beginning to end of digestion, but curves such as he describes must be uncommon, as we have seen very few out of a very large number of investigations. The evidence available at the present time seems to point to the conclusion that neutral chloride under certain circumstances escapes transformation into HCl, and that the acidity of the gastric juice varies to a moderate extent with the rate of secretion after the fashion of the inorganic salts of the saliva, but such occurrences can in general only play a minor rôle in the regulation of the acidity of the gastric contents when the gastric secretion is normal.

The relaxation of the pylorus occurs at a definite time during digestion, varying in individual cases, and must be regarded as a definite link in the chain of events, which constitutes the normal digestive process. It is quite true, as Ryle[26] has pointed out, that in addition to pyloric relaxation there must also be a simultaneous adjustment of intragastric and intra-duodenal pressures, so that the pressure in the pars

pylorica must fall below the pressure in the duodenum. In order to obtain more definite information of this process, therefore, Salmond and myself [27] have recently studied the movements of the duodenum as carefully as possible by the X rays in a series of normal persons, and also in patients suffering from functional disturbance only or in addition organic disease. We found that in 93 per cent. of the cases examined the duodenum exhibited to different degrees the movement of antiperistalsis, which we regard as being a normal condition. Sometimes this movement is definite and clear, sometimes it is ill-marked and indistinct, sometimes it is imperceptible. It has the effect of swinging back the food which frequently may be seen to distend the cap, being held up by the pylorus. Each food mass may swing backwards and forwards several times or once only; or the movement may be only occasionally seen. It occurs independently of duodenal or gastric peristalsis or relaxation of the pylorus, but the important point is that the duodenal cap is filled under pressure not only by the stomach, but also by the duodenum, and the only barrier to regurgitation into the stomach is the pyloric sphincter. Now it is quite clear that regurgitation cannot occur into the stomach when the pylorus relaxes before a gastric peristaltic wave, as the intragastric pressure rises to 30 cm. water or higher at this time, and the mean pressure in the duodenum is not higher than 10–15 cm. water (Marbaix [28]) or 14–20 cm. water (Payne and Poulton [29]). The mean intragastric pressure, however, is commonly below 10 cm. water, so that regurgitation could quite easily occur between peristaltic waves. We are bound to assume that in the early stage of digestion the pylorus relaxes only before gastric peristaltic waves, but that as digestion proceeds and the acidity attains its normal height, the pylorus begins to relax independently of peristalsis and if the cap is full at this time regurgitation back into the stomach occurs. That this is the case is evident from the fact that we observed regurgitation in six cases between gastric peristaltic waves, the food being seen to pass right back into the stomach through the cap owing to the impetus imparted to it by the second part of the duodenum. It is probable that this type of mass regurgitation only occurs when the pylorus happens to be open during a vigorous antiperistaltic wave.

In a later series of observations Salmond has noticed regurgitation of another kind, which is perhaps that most commonly occurring. This occurs during both a passive and an active phase of the cap. In the former whilst the cap remains distended and between peristaltic waves a thin stream of barium may be seen to run back into the stomach, in the latter a contraction of the cap beginning at the peripheral end produces the back-flow. At the present moment all that can be definitely stated is that the fact of regurgitation has been established by the X rays, but nothing more definite can be said about it. Antiperistalsis of the duodenum delays the food and holds it up in that structure, thereby establishing conditions favourable to regurgitation back into the stomach when the pylorus relaxes at a favourable moment. Apperly [21] has recently brought forward evidence to show that the control of the pylorus in thus permitting regurgitation ultimately depends upon the salt values of the duodenal fluids.

In the empty stomach the tone of the pyloric sphincter is low, and it may remain open for many minutes at a time, relaxing quite independently of peristalsis. The small amounts of gastric juice which are secreted are expelled periodically into the duodenum, and regurgitation back into the stomach of gastric, pancreatic, and other juices likewise occurs, and these form the mixed secretions found in the fasting stomach to the amounts of 30 c.cm. or 50 c.cm. This is the condition of the pylorus in the fasting stomach, and at the height of the acid curve during digestion it begins to return to this state as the stomach empties. In the condition of irritability the pylorus refuses to commence this independent relaxation at the usual time, and the acid curve continues to mount as the concentration of HCl in the gastric contents increases. In a certain number of patients the stomach empties very rapidly and the food is shot through the duodenum without being held up. Regurgitation cannot take place in such cases, and a climbing curve results.

Although we cannot usually show in any one individual all the phases in the action of the pylorus from the onset to the cure of his complaint, sometimes however, we are fortunate enough to meet with such cases, and there can be no doubt whatever that pyloric hypertension occurs to different degrees, for different times, and irregularly in the same patient, so that one must not expect every case to give a typical curve of defective neutralisation. In the case of a patient, who worked out many curves upon himself and who suffered from pyloric pain, the normal curve was that which he most constantly showed when in an interval of freedom, and a curve of deficient neutralisation when in a period of illness. He used an electrical method and therefore only extracted small quantities each time. Although there was no pain during the examinations one would have expected, with a rising acid curve, some slight prolongation of the emptying time as seen in Figs. 10 and 11. This is probably due to the difficulty of accurately determining the emptying time when a full mixed meal is used, unless the stomach is washed out (Figs. 16 and 17).

In a series of 138 cases of fractional test-meals 101 showed pain in isolated positions and 37 in combined positions. There are three groups of curves: (1) normal; (2) deficient neutralisation (=pyloric hypertension; (3) excessive neutralisation (=pyloric hypotension). The analysis of the 101 cases is as given in Table III.

TABLE III.

Position of pain.	Curves.			Total.
	Normal.	Defective Neutralisation.	Excessive Neutralisation.	
Upper sternum ..	—	1	—	1
Lower sternum ..	3	—	—	3
Upper st.-umbilical	27	19	5	51
Middle "	5	9	—	14
Lower "	2	20	—	22
Right 9 c.c. ..	3	2	—	5
Left 9 c.c.	1	1	—	2
Right and left 9 c.c.	—	3	—	3
	41	55	5	101

Combining the areas together we obtain the following:—

Part affected.	Pylorus.			Total.
	Normal.	Hypertension.	Hypotension.	
Cardiac region ..	27	19	5	51
Pyloric region ..	11	35	—	46
Œsophagus ..	3	1	—	4
	41	55	5	101

In this series pyloric hypertension occurred in 37·2 per cent. of cases with cardiac pain, in 76·1 per cent. of cases with pyloric pain, and in 25 per cent. of cases with œsophageal pain. This series of cases, therefore, strongly supports the view that the hypothesis formed above of the probable course of pathological events giving rise to the pyloric syndrome is correct; and also that both cardiac and œsophageal pain are often secondary to the pyloric hypertension occurring in this condition, because the percentage 37·2 is higher than should occur in a normal series. The number of œsophageal cases are too few to be reliable, but curves are not as a rule done in such cases. The cases of hypotonic pylorus belong to the cardiac group of cases.

Turning our attention now to the amount of gastric juice secreted. Of 54 cases of diminished secretion 32 affected single areas and 22 combined areas. An analysis of the 32 cases is as shown in Table IV.

TABLE IV.

Position of pain.	Time of onset.				Cases.
	At once or quite soon.	½–1 hr.	1 hr. up.	Irreg.	
Upper sternum ..	—	—	—	1	= 1
Lower sternum ..	—	1	3	—	= 4
Upper st.-umbilical	3	8	3	2	=16
Middle „	2	2	1	4	= 9
Lower „	1	—	1	—	= 2
Total	6	11	8	7	=32

It appears that in diminished secretion of gastric juice the body of the stomach is more likely to be affected than the pyloric end. With regard to the time of onset of symptoms, in only a quarter of the cases did the pain begin later than one hour after eating. If all cases are combined together in respect of this point the following result is obtained :—

—	Time of onset.				Cases.
	At once.	½–1 hr.	1 hr. up.	Irreg.	
All areas and combinations ..	13	16	14	11	=54

So that not only is the body of the stomach more often affected when the secretion is diminished, but the symptoms tend to occur irregularly and in the early period of the digestive process. There is no primary form of functional disturbance of the stomach due to a diminution of gastric juice ; so long as the stomach empties normally there are no ill-effects or secondary symptoms, but if delay occurs bacterial fermentation of carbohydrates may occur if the free HCl falls below 0·07 per cent. Any marked degree of dilatation of the stomach or bacterial fermentation is, so far as I am aware, unknown in functional disturbance of the stomach.

It is doubtful if hypersecretion of the gastric juice is ever a primary cause of functional disturbance of the stomach. A digestive hypersecretion in which amounts above the average normal are secreted during digestion and which may outlast this act for varying times is common enough, especially in duodenal and pyloric ulcers, and is recognised by a rapid rise in the total chloride curve when the stomach is full and emptying normally, or sometimes by the continuance of the secretion when the stomach is empty ; it is, however, uncommon to find large amounts of juices in the fasting stomach, most amounts being well within the average limit of 30 c.cm. Clinically such cases differ in one respect only from those in which no such increase occurs, and that is in the eructation of fluid in larger quantities than usual. The question arises whether the so-called periodic hypersecretion—that is to say, paroxysmal attacks of hypersecretion of gastric juice—ever gives rise to symptoms which entitle it to be styled an independent affection. It is quite true that there are cases in which attacks of pain and the vomiting of large quantities of watery fluid of varying degrees of acidity occur, and that in such cases no signs of any nervous disease are present or of any cause which might produce a reflex effect upon the stomach. It is, however, impossible to speak of such cases as gastric neuroses unless they have been shown free from organic disease by operation, a state of affairs I have not yet personally seen. My view would be that it is not yet proved that any alteration in the secretion of gastric juice could be described as constituting a primary functional disturbance of the stomach, although, when present, both a diminution and an increase in the gastric juice undoubtedly modify the gastric symptoms present in the different forms of dyspepsia in which they occur.

B. CARDIAC SYNDROME.

The body of the stomach shows the important difference from the pyloric end that the symptoms due to its disorder are manifested during both phases of activity of the stomach. They are due to incapacity on the part of the body to accommodate itself to the volume of its contents whilst it is being filled or emptied. In the former case the lengthening reaction and in the latter case the shortening reaction of its muscular fibres is interfered with, and their contraction tension is raised.

Causes.

1. In order that the stomach may accommodate itself in the normal fashion *whilst it is being filled* with food, two conditions must be fulfilled. The food must not be eaten too quickly and the muscular coat must be able to respond in the normal manner.

(*a*) The first cause of the cardiac syndrome, therefore, is bolting of the food. Now a great many people bolt their food with impunity, or occasional feelings of fullness only, but sooner or later, depending upon the make up of the nervous system of the individual, the muscle becomes irritable, reacts too strongly, and an attack of dyspepsia supervenes.

(*b*) The second cause is either irritability of the neuro-muscular mechanism or the so-called atony.

Irritability is brought about in one of the three ways I have already mentioned in the case of the pyloric region. (1) A local focus of irritation to the myenteric plexus as an ulcer of the body of the stomach, or a general irritability produced by acute gastritis. (2) Reflex irritation from some other portion of the digestive tract, and about this we know less than in the case of the pylorus, except that it no doubt occurs. (3) Instability of the central nervous system, on the other hand, is of the greatest importance as a cause of irritability of the body of the stomach. This effect is no doubt exercised through the vagus. There is in all cases some slight cause, probably sometimes no more than a mere exaggeration of the normal movements or sensation. The condition becomes exaggerated and persists as a chronic irritability.

Atony of the stomach in the old sense as a primary condition probably does not exist, but there can be little doubt that in conditions of debility the stomach may be hypotonic as a part of this condition. It is difficult to prove this statement because it is never of any marked degree. As a secondary effect it does not lead to much dilatation of the stomach. The X rays have shown that all cases of marked dilatation are obstructive. Inhibition of the stomach, as Cannon has shown experimentally, may be produced both reflexly and by emotional disturbance. Such conditions in clinical medicine are undoubted and perhaps more as temporary than chronic effects.

2. *As the stomach empties* this condition of neuro-muscular irritability again interferes with the function of accommodation sooner or later during digestion, the exciting cause being the condition of the gastric contents.

In addition to these primary causes the body of the stomach becomes irritable as I have described, or atony may supervene secondary to pyloric irritability.

EFFECTS PRODUCED.

1. *Filling of the Stomach.*

When the normal stomach is *filled too rapidly* with food the muscular fibres are unable to undergo the normal lengthening reaction, and react too strongly, with the result that the intragastric pressure rises, the contraction tension is raised, and a sense of fullness results. After a time as the stomach empties accommodation occurs and the symptom disappears.

When the condition of *irritability* has supervened in any of the ways already indicated and the irritability is excessive the accommodative power of the

stomach is also interfered with. Although the stomach is filled normally the reflex tonic reaction is at once excited and a feeling of fullness or pain is experienced within a few minutes of eating the meal. During the actual consumption of the food there is, as a rule, no pain, and if pain is present it is often temporarily relieved. The explanation is that as the food enters the stomach the relaxation of the cardiac sphincter is accompanied by a receptive relaxation of the body of the stomach through the vagus.[30] It is only temporary and when the meal is finished excessive contraction of the stomach occurs. Such patients may feel quite full after eating small amounts and so they reduce the quantity of their food accordingly. This does not produce the desired result, because owing to the absence of the normal stimulus to the lengthening reaction, the stomach contracts all the more and similar to what occurs on experimental section of the sympathetic. The result is wasting due to insufficient food. Even though the stomach empties rapidly pain may be constantly present and occur in the empty stomach; this must be regarded as due to excessive hunger contractions, the central nervous system being hyperæsthetic. It is more particularly in these nervous conditions that emotion is likely to bring on irregular attacks of pain.

By *atony* is probably meant some degree of loss of tone in the muscle-fibre associated with irritability—in other words, a condition of irritable weakness. Accommodation is defective because the muscular fibre is already relaxed, and when food is put into the stomach a certain amount of tonic reaction occurs at once as the threshold for this reaction is lowered, and the feeling of fullness results. Pain is never present, because the muscle is unable to recover its tone sufficiently to increase materially the contraction tension.

2. *Emptying of the Stomach.*

The function of the body whilst the stomach is emptying is to maintain a constant pressure upon the food, which keeps the pyloric vestibule full. So that it not only acts as a reservoir, but is also the filler-up of the pyloric region. The pressure in the body of the stomach is maintained at a constant level, by the capacity the muscle-fibres have of undergoing a shortening reaction without any increase of their contraction tension. The empty stomach is contracted up and contains a certain amount of air and mixed secretions. Boldyreff [31] first showed that rhythmical contractions occur periodically in the empty stomach, which Cannon and Washburn [32] demonstrated as being the cause of hunger sensations. Carlson [8] has further analysed these movements in detail and shown that two distinct types of movement occur. The first is a tonus rhythm affecting all parts of the body in which the tone increases and diminishes, this alternation continuing constantly without cessation. The second is peristalsis which begins near the cardia and traverses the whole body and pyloric region. When the stomach is filled these two movements cease and the body of the stomach is apparently quiescent, its only action being the steady pressure maintained by its tone. After a short time shallow peristaltic waves appear at the fundus and in about half an hour a tonus rhythm may be demonstrated at the cardiac end. The tonus rhythm and peristaltic waves increase in intensity as digestion proceeds, and continue as those of the empty stomach described above. So that in addition to maintaining its steady grip upon the diminishing contents the body shows rhythmic increase of tone and peristalsis after a period of quiescence.

When the neuro-muscular mechanism is irritable these movements are exaggerated—that is to say, there is a general increase of the tonic contraction, with increase of the tonic variations which no doubt amount to gastrospasm in some cases. The symptoms due to these exaggerated contractions will be likely to commence when the body really gets to work, i.e. about half an hour after eating, but they may appear at any time up to about two hours later since the acidity is rising and the gastric contents becoming increasingly irritating. They will not be likely to begin later since the gastric contents will have materially diminished in volume and the wave of neutralisation commenced, for the pylorus will be acting normally. Variations naturally occur, for in some cases the food leaves the stomach rapidly and now the symptoms will be shorter and less severe. If pain occurs later than about two hours after food it may be concluded that the pylorus is beginning to hold up the contents. The earlier the pain comes on the more likely is it to depend upon irritability due to the central nervous system, and the later it appears the more it depends upon the irritating and acid gastric contents. Alkalis will remove the symptoms in these cases.

Owing to the increased pressure in the body œsophageal regurgitation is liable to occur as in the pyloric syndrome. The fluid may be acid if neutralisation has not yet occurred, but it is more often bitter or neutral since the acidity of the contents is lower than in pyloric cases. The patient is more neurotic and more likely to eructate gas voluntarily. This type of case produces no effect whatever upon the acidity of the gastric contents nor upon the digestive process. When food is eaten the movements are inhibited, a lengthening reaction takes place in the muscular fibres, and the pain ceases. This is not always the case nor does it occur so regularly as in pyloric cases, for relaxation occurs less easily when the muscle is very irritable, but even when pain comes on in half an hour after food it is not uncommonly relieved. When the stomach is hypotonic there is no pain but sometimes fullness, for the muscle is unable to recover its tone sufficiently to increase materially its contraction tension. As the stomach empties owing to the loss of tone the pyloric end is not kept normally filled so that the emptying time is delayed. The symptoms disappear as the contents become less. The tone of the cardia is lessened and eructation and air-swallowing facilitated, which symptom depends upon the state of the nervous system of the patient.

C. Œsophageal Syndrome.

Œsophageal symptoms are due to the presence of liquid or solid material or gas, which give rise to reflex tonus rings and peristalsis. Their presence is accounted for by regurgitation from the stomach or by abnormal deglutition—that is to say, bolting the food and gulping down liquids. We know very little indeed about reflex nervous effects upon the œsophagus, but there can be no doubt that the influence exerted by the central nervous system is very marked.

Regurgitation into the œsophagus tends to occur whenever the intragastric pressure rises as the result of increase in muscular contraction or external pressure as in voluntary eructation, and is only prevented by the tone of the cardiac sphincter, which follows that of the body of the stomach. This tone is normally low, for an intragastric pressure of 25–30 c.cm. of water is enough to overcome it. However the regurgitation is produced the effects upon the œsophagus are the same. Speaking broadly, the effects are modified by the degree of acidity of the gastric contents and the condition of the œsophagus as regards irritability. Cannon [33] has demonstrated experimentally the course of events when a fairly full liquid meal is administered to the cat. So long as the contents are neutral the liquid regurgitates at each relaxation of the cardia three or four times a minute, but when the gastric contents become acid the regurgitation ceases owing to increased tone of the sphincter. Each time regurgitation occurs the fluid is held up by the cardiac sphincter and passed back into the stomach by reflex peristaltic waves originating in a tonus ring produced at the upper end of the fluid. It is common enough to witness the same series of events by the X rays in patients after a full meal and when lying on the back, without their experiencing any sensation whatever. This is the usual result when the nervous system is normal and the œsophagus not irritable, unless the gastric contents are acid in reaction, as, for example, during the later stages of

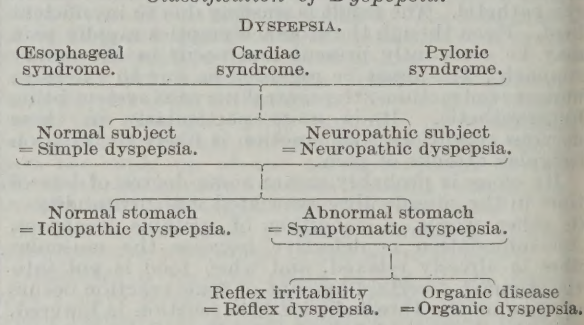
digestion in the condition of pyloric irritability. In such a case repetition of the regurgitation after a time leads to irritability of the muscular coat and mucous membrane of the œsophagus, and the fluid is held up for longer periods by persistent hypertension of the cardiac sphincter. Increased tension is maintained in the œsophagus by persistent ring spasms at various points. Tightness or aching is thus produced in the lower chest, and a burning sensation may be imparted to it by the hypersensitive mucous membrane and twinges of referred pain may occur in the jaw. Severe pain at the ensiform is now and then experienced from spasm of the cardia and lower œsophagus. Swallowing water will relieve the feelings by clearing the œsophagus.

When the patient is neurotic other symptoms are liable to occur whatever is the reaction of the gastric contents. These are due to the hypersensitive condition of the mucous membrane, to the ready and persistent response of the œsophagus to stretching, to the efforts at voluntary eructation, and excessive voluntary swallowing movements. The effects of the latter, although they may on occasion temporarily remove the œsophageal contents are, on the whole, to maintain the condition. In the normal individual the cardiac sphincter does not relax before each peristaltic wave, particularly if saliva and air alone are swallowed, so that in these patients the contents, chiefly air and some liquid, tend to be held up, unless the sphincter relaxes before the swallowing of food or is forced by the voluntary efforts of the patient, a feat he is by no means always able to perform. The air is retained in the œsophagus by a ring spasm at the upper part and a constant lump or tightness is felt in the upper sternum, which the patient often tries to swallow. The air moves up and down the œsophagus in response to ineffective reflex peristalsis, and such patients may feel the sensations shift up and down. Sometimes exaggerated peristalsis occurs with every meal and the patient feels his food pass all the way down like a series of lumps; or the hyperæsthetic mucous membrane causes a burning or soreness throughout the whole length of the œsophagus.

Abnormal deglutition as a primary cause of œsophageal symptoms is due to imperfect mastication and lubrication of the food and rapid swallowing. The food passes down the œsophagus slower than normal, as first shown by Hurst [34] with the X rays, and according to him it may take 15 minutes to descend in place of the normal 8 to 18 seconds. Several pieces may be seen in the œsophagus at the same time; occasionally it may stick for a long time at the level of the bifurcation of the trachea and even be regurgitated. The cardia may hold up the food, and in one of my patients a piece of meat was fished up from the lower end of the œsophagus. I am quoting cases who after some years are now in perfect health.

Œsophageal peristalsis is a reflex act which is initiated by a single afferent impulse started by the contact of the food with the back wall of the pharynx and adjacent areas. This single impulse is sufficient to ensure the completion of the act of swallowing. It spreads in the deglutition centre evoking a series of motor discharges which pass through the vagi to the œsophagus. What is particularly important from our point of view, however, is that œsophageal peristalsis may be initiated at any point in its course by local stimulation. A foreign body in the œsophagus as shown by Carlson,[8] if it causes a certain degree of distension, will produce a local contraction lasting up to a few minutes at the point where it is lodged; from this local ring spasm peristaltic waves are sent down the œsophagus periodically till the body is removed. A voluntary deglutition will start off these movements again when they have quieted down. This form of tonic contraction is due to a reflex through the vagus. Cannon [35] has shown experimentally that the lower portion of the œsophagus, the muscular coat of which entirely consists of unstriped muscle, is able to take on an automatic action, when the vagi are cut. When the wall is stretched by food a ring constriction appears and from this peristaltic waves pass down and clear the œsophagus; these movements occur as the result of local reflexes through Auerbach's plexus. This temporary retention of food and gas in the œsophagus through the ring spasms produced causes tightness and pain in the chest soon after meals. The normal peristalsis of the œsophagus when a meal is eaten properly clears away the material and relieves the symptoms. In the patient of stable nervous system such symptoms are of little moment and only occur when the individual in question is indiscreet. If the bolting of food becomes a customary proceeding or the patient is neurotic, the œsophagus becomes irritable and hypersensitive and more easily responds to stimulation. Voluntary eructations and swallowing movements add to the air in the œsophagus, and all the other phenomena develop which I have already described.

Classification of Dyspepsia.



The symptoms included under the term dyspepsia are due to altered nerve reflexes and vary in accordance with the excitability of these reflexes, which in turn depends upon the stability of the central nervous system. Individuals vary very considerably in this respect and many grades exist between the average normal person and the neuropath, so that the symptoms constituting dyspepsia must be classified according to the stability of the nervous system of the subject of them.

1. NORMAL SUBJECT.

The nervous system of this type of individual is normal, and the normal stimulus of food gives rise to a normal motor response, with little or no sensory accompaniment.

The functional disturbance of the stomach from which such a person suffers is of the *physiological order*—that is to say, an abnormal stimulus gives rise to an increased motor response with sensory accompaniment. Such a condition may be called *simple dyspepsia*, and this includes three fundamental groups of symptoms:—

1. *Pyloric syndrome* in which the symptoms are due to irritation of the pylorus, with secondary effects upon the body of the stomach and the œsophagus.

2. *Cardiac syndrome* in which the symptoms are due to irritation of the body of the stomach with secondary œsophageal effects.

3. *Œsophageal syndrome* in which the symptoms are due to primary or secondary irritation of the œsophagus.

The symptoms are characterised by order and regularity in their appearance and disappearance and are clearly indicative of the region affected. They occur at stated times during digestion when the irritable part is brought into action, and cease when its task is ended. They are easily relieved by removing the abnormal stimulus—that is to say, by dieting the patient. The pyloric syndrome is particularly characteristic of this type.

2. NEUROPATHIC SUBJECT.

The functional disturbance of this type of person is of the *pathological order*—that is to say, a *neurosis*. There are two groups of cases.

1. The increased motor and sensory response may persist after cessation of the abnormal stimulus. This condition is

n advanced stage of that described as simple dyspepsia. ll patients do not proceed to it, but only those who are of neuropathic tendency or have acquired it by exhaustion, verstrain, overwork, and worry, and especially those uffering from the cardiac and œsophageal syndromes. The ain appears sooner than it did before or irregularly, and is nfluenced by emotion, nerve strain, and other occurrences f everyday life, but is not so easily relieved by food. ttacks are easily precipitated and are not so easily relieved y treatment as formerly. Voluntary interference on the art of the patient also tends to obscure the syndrome.

2. In the second group the patient is definitely neuro-athic, but there is always some initial disorder, however ivial, which may soon be overshadowed, since there is wering of the threshold of excitability leading to constantly creased motor and sensory disturbance, the stimuli being ormal. The cardiac and œsophageal syndromes are those ost constantly present, but all the parts may be affected equal degree simultaneously or irregularly. Disorder and regularity are characteristic of this type, and symptoms ay be present in the empty stomach. In some cases the atient begins to interpret his symptoms variously and equire exaggerated motor and sensory symptoms depending n his ideas of what they should be. The symptoms thus lose eir localising value. Isolated symptoms are developed such eructatio nervosa, anorexia nervosa, or perversions of petite, nervous vomiting, nervous nausea, painful empti-ss, transient obstruction of the œsophagus; in fact, any mptom may become an obsession or a phobia.

These syndromes occur in three different types of omach.

(*a*) The stomach may be *normal*, and in this case e causes of these disturbances are twofold:—

1. The quality or quantity of the food or drink; its mode preparation; or the presence of irritants in it.

2. The mode of filling the stomach, in which both mastica-n and deglutition are concerned.

The disorders are more easily excited in the omach in individuals who are the subjects of some ronic illness, such as anæmia or an infective process intoxication.

(*b*) The stomach may be the seat of *organic disease*.

1. The disease—for example, ulcer—acts as a focus of itation to the part of the stomach in which it is situated d the same syndromes as in simple dyspepsia are produced the food. The patient commonly has no symptoms when ing a regular life and on a plain diet, but if either of ese conditions is unfulfilled the position of the disease termines the resulting syndrome. The syndromes are aracterised by great regularity in the pain and its recur-nces, and by its severity and long continuance. If the tient is neurotic the regular symptoms are overshadowed d the condition becomes unrecognisable.

2. If the stomach is structurally altered, so that the motor nctions are interfered with as in pyloric obstruction or ncer, the disordered functions are so pronounced as to nstitute special indications of the disease in question. e X rays and other tests afford valuable aids or conclusive oof of the existence of organic disease.

(*c*) The stomach may be the subject of *reflex itability* from some other part of the body, more rticularly of the alimentary canal, the chief causes ing the gall-bladder, the intestines, and the pendix. The symptoms are produced by the food d the resulting syndrome depends upon the part of e stomach irritated and the time when the irritation most marked.

THE EARLY DIAGNOSIS OF CANCER OF THE COLON AND RECTUM.*

BY ARTHUR F. HURST, M.D. OXF., F.R.C.P. LOND.,
PHYSICIAN TO GUY'S HOSPITAL,
TERENCE W. TURNER, M.R.C.P. LOND.,
AND
JOHN F. VENABLES, M.D. OXF.,
ASSISTANT PHYSICIANS TO NEW LODGE CLINIC, WINDSOR.

THE early diagnosis of carcinoma of the colon depends primarily upon the ability of the practitioner to obtain an accurate history of the patient and to recognise what symptoms should lead him to suspect that this disease is present. By the time that the first symptoms appear a growth is likely to have attained such a size that a definite diagnosis can be made by means of the X rays, the sigmoidoscope, and examination of the stools, or, in the case of the rectum, by digital medical examination.

The table gives the duration of symptoms at the time of admission into New Lodge Clinic for diagnostic purposes of 25 consecutive cases of cancer of the colon and rectum.

Table showing Duration of Symptoms in Twenty-five Cases sent for Diagnosis.

Cases.	Duration of symptoms in months.	Cases.	Duration of symptoms in months.

2	5	1	24
4	6	1	36
1	8		

The case in which symptoms had been present for three years was one in which malignant degeneration had occurred in a group of polypi in the descending colon. As an early diagnosis and operation might have prevented the development of carcinoma, there is no reason why it should not appear in the table.

*An abstract of this paper was communicated to the Proctological Section of the Royal Society of Medicine on May 3rd.

The average duration is 10½ months, or 9½ months if the case of polyposis is excluded. It is clear, therefore, that the prospects of radical cure by operation would have been very different if all the patients had been sent for investigation directly they complained of suspicious symptoms.

The two earliest symptoms are abdominal discomfort or pain and a change in the habitual action of the bowels. Both symptoms were present in almost all our cases. The discomfort or pain is localised in the segment of bowel proximal to the obstruction. It is a small intestine pain and is felt in the neighbourhood of the umbilicus in cancer of the cæcum. In cancer of the ascending colon or hepatic flexure it is felt on the right side of the abdomen, and in cancer of the splenic flexure, descending, and iliac colon, and the proximal part of the pelvic colon, it is felt on the left side. Pain produced in the middle segment of the transverse colon is felt just below the umbilicus, and that caused by growths in the distal part of the pelvic colon or pelvi-rectal flexure are localised in the middle line between the umbilicus and pubes. The pain is often colicky, and its disappearance may coincide with a gurgle which can be heard and felt; this is a most significant symptom, which may enable the patient to localise the site of obstruction with great accuracy.

In 9 out of 25 cases the patient had become more constipated and in 6 he had complained of diarrhœa; in 8 cases there was alternately constipation and diarrhœa, or an initial attack of diarrhœa followed by persistent constipation. It is necessary to add that in cancer of the rectum and pelvic colon the diarrhœa is of a spurious type, examination of the stools showing that solid fragments are mixed with the semi-liquid fæces. In only two cases had no change in the habitual action of the bowels been observed.

In contrast with carcinoma of the stomach general symptoms are rarely observed in the early stages. The patient may feel quite fit, with a good appetite and undiminished energy. No anæmia is present and no weight is lost. In only one of this series of cases and in one other earlier case were general symptoms present without intestinal symptoms. The patients were anæmic and complained of anorexia and loss of energy. As occult blood was found in their stools and complete achlorhydria was present, carcinoma of the stomach was diagnosed, though the X rays had shown no abnormality. A growth of the ascending colon was, however, found in one case and a growth of the splenic flexure in the other.

Radiological Diagnosis.

An opaque enema is of great value in demonstrating the site of any obstruction in the colon, as one of us first showed just 20 years ago. It is a curious fact that the enema may be temporarily or permanently held up by an obstruction, which leads to no obvious delay in the passage of an opaque meal. The actual passage of the fluid should always be watched, as a slight obstruction may lead to only a temporary delay in the passage of the fluid, caused possibly by spasm. The point where any delay is observed should be palpated under the screen, as it is not uncommon for a small tumour to become palpable when one's fingers are directed to its exact localisation. Before accepting the apparent "hold-up" of an enema as evidence of a stricture, the patient should turn on to his face, as the fluid occasionally passes on in a normal manner when this is done.

A good radiogram may show the nature of the obstruction, as the narrowing caused by adhesions, diverticulitis, and a fibrous stricture following ulcerative colitis all give appearances which are to some extent characteristic and differ from the irregular jagged outline of that produced by a growth. A filling defect is sometimes recognisable in the complete absence of any obstruction.

It is very important to remember that early cases of carcinoma of the colon may show no filling defect and cause no obstruction to the passage of an opaque meal or opaque enema. In 1909 and again in 1915, before we fully realised this, one of us rejected the diagnosis in two cases, in which the symptoms had made him suspect a growth of the colon. Within three months a tumour became palpable in both cases; the delay in advising operation may have been the cause of the subsequent recurrence.

As a definite diagnosis had been made by rectal and sigmoidoscope examination in 5 out of the series of 25 cases, an opaque enema was given in only 20. It showed obstruction in 14 of them and a filling defect without obstruction in the others; in four of the former an opaque meal also showed obstruction. In one case the meal showed obstruction four inches above the level of the iliac crest, where the opaque enema had been obstructed; corresponding with this the growth was found to have formed the head of an intussusception four inches long. In one case an opaque meal revealed an obstruction which was not shown by an enema, and in one case neither enema nor meal showed any abnormality.

The Stools.

The presence of mucus with a solid stool is of no clinical significance, but blood or pus, with or without mucus, is always an indication that further investigations are required. If associated with entirely fluid or semi-fluid stools, ulcerative colitis is in all probability present, but if in addition fragments of solid fæces are found, even if the patient complains of "diarrhœa," a growth of the pelvic colon or rectum is a more likely diagnosis, but visible blood and pus are hardly ever observed when the growth is proximal to the pelvic colon.

When no abnormal constituents are recognised with the naked eye the patient should be given a farinaceous and chlorophyll-free diet and some charcoal. As soon as all the charcoal has been passed the stools should be examined chemically and spectroscopically for occult blood. In our experience this is present in all or almost all specimens in every case of cancer of the stomach and of the colon. Obvious blood was present in the stools in four cases involving the rectum and in one out of eight involving the pelvi-rectal flexure, but in only one other—the growth of the iliac colon which had formed a chronic intussusception. Occult blood was found in all the remaining 19 cases. In each case a positive guaiac reaction was obtained; in four this finding was confirmed by an extract giving a spectrum of hæmatoporphyrin alone, in three of acid hæmatin alone, and in two of both hæmatoporphyrin and acid hæmatin. The acid hæmatin spectrum is of special importance, as it is rarely seen in cancer of the stomach or ulcer of the stomach or duodenum except after a large hæmorrhage, and it is then always accompanied by the spectrum of hæmatoporphyrin. Of the 19 stools containing no obvious blood four had some excess of mucus, and in two of these and one additional case the patient had occasionally noticed traces of blood before admission to the clinic.

Occult blood is rarely found in uncomplicated diverticulitis and never in constipation or diarrhœa unaccompanied by organic disease. Curiously enough a local band of adhesions involving the colon may also lead to the constant presence of occult blood in the stools. As this condition sometimes gives rise to symptoms and radiological signs indistinguishable from those caused by a growth, the differential diagnosis may be impossible, though there is generally a longer history or illness, the details of which often point to the probable cause of the adhesions. Fortunately it does not greatly matter if a mistake in diagnosis is made, because this type of adhesion is the one form which can generally be dealt with satisfactorily by operation.

Sigmoidoscopy.

It is unnecessary to say anything before the Proctological Section about the value of the sigmoidoscope in the early diagnosis of carcinoma of the pelvi-rectal flexure and pelvic colon, but we should like to suggest, as we have often done before, that it is time that the

profession as a whole learnt to use this instrument, which should no longer be regarded as one which should only be handled by the proctologist. Nobody thinks of diagnosing pharyngitis without direct inspection of the pharynx; nobody should think of diagnosing hæmorrhoids or colitis without digital examination of the rectum and direct inspection of the colon. If this rule were always followed the lives of many patients, who now reach the surgeon too late for radical operation, would be saved. The President of the Section doubtless remembers performing a colostomy on a patient in whose rectum we had found a large inoperable growth; he had seen no less than five medical men within three months of consulting us, not one of whom had made a rectal examination. We have also seen a number of patients with growths of the rectum or pelvic colon, who had just undergone a course of Plombières douches at a British or Continental spa, in whom a digital or sigmoidoscopic examination would have at once revealed the nature of their disease. For successful sigmoidoscopy neither an anæsthetic nor a previous injection of morphia is ever required, and the patient should, if possible, be examined without any preparation by aperients or enemata.

In the present series of 25 consecutive cases a tumour was palpable on abdominal examination in six, in one of which it was only discovered whilst palpating a visualised filling defect under the screen during an X ray examination. In all four cases of rectal carcinoma the tumour could be felt on ordinary digital examination, and in one case involving the pelvic colon it was felt through the anterior rectal wall. The pelvi-rectal flexure, which is the commonest of all sites of carcinoma of the bowel, is situated 4½ inches from the anus and has only a very small range of movement. A growth in this situation is therefore beyond the reach of a finger inserted *per anum* and is only rarely palpable on abdominal examination, but it can easily be recognised with the sigmoidoscope, as it was in the eight cases in our series. In seven cases the tumour was beyond the reach of the sigmoidoscope and was also so small or, in the case of the splenic flexure, situated so high up under the left costal margin that it could not be felt on abdominal examination.

If all cases of suspected carcinoma of the colon were sent for diagnosis within a month of the onset of symptoms many patients would be advised to undergo an operation when the evidence was still inconclusive. But an occasional unnecessary exploration will be more than compensated for by the infinitely better prospects of permanent cure, which will be present if the average duration of symptoms is one instead of ten months when the patient is sent to the surgeon. The surgeon also should be prepared to act upon the indications given by the physician. In 1922 a man of 52 was sent to us with a short history of constipation and attacks of colicky pain in the region of the splenic flexure. Nothing abnormal was felt on abdominal examination and an opaque enema revealed no filling defect nor obstruction, but an opaque meal was held up at the splenic flexure for 48 hours. The stools constantly contained occult blood. A diagnosis of early carcinoma of the splenic flexure was made and the patient was advised to undergo operation. Being dissatisfied, he consulted a well-known London surgeon, who removed his appendix. As no improvement followed the same surgeon six months later divided adhesions which had formed in connexion with the first operation. In 1925, just over three years after we had diagnosed a growth of the splenic flexure, acute obstructive symptoms developed, and the surgeon, who had ignored our advice, now found an inoperable growth of the colon in the exact position we had originally indicated.

We have said enough to show that the early diagnosis and successful treatment of cancer of the colon depend upon timely coöperation between the general practitioner, the diagnostic team, and the surgeon.

OF HALLUCINATIONS.

By H. MARK PALMER, M.R.C.S. Eng.,

RESIDENT MEDICAL OFFICER, CASSEL HOSPITAL FOR FUNCTIONAL NERVOUS DISORDERS, PENSHURST.

The Note on Night-terrors, by Dr. J. W. Shackle, in The Lancet of Feb. 11th, is of great interest to students of psychological medicine, for this disorder is an example of the interaction of psychological and physiological processes. Physicians know well that a physical illness is always associated with a certain degree of mental change, whether it be only a slightly biased outlook on life, generally during the illness, or a more severe and prolonged alteration. There is also a growing amount of evidence that diseases which seem to originate in the mind, such as anxiety states, compulsion neuroses, and possibly psychoses, if not checked, end in physical changes which may go on to organic disease. When the signs and symptoms of an illness suggest that one or more of the body organs is out of order the line of treatment may be clearly indicated. The same may be said of psychical illnesses, but there is a small group of diseases which it is difficult to class, for their signs and symptoms reveal both psychical and physical disturbances, which may have the same origin. This group contains night-terrors, epilepsy, migraine and perhaps psychoses. Primary psychical illnesses such as the neuroses may have had their beginnings, as Alfred Adler suggests, in inherited organic weaknesses and subsequent psychic over-compensation, resulting in excessive emotional strain, and so giving rise to unduly accentuated anxiety, sorrow, grief, disappointment, or alarm. Unlike the neuroses this group seems to have its origins in neuronic instability, although the manifestations might equally indicate a psychical cause. Indeed, some psychologists apparently believe that even epilepsy, which shows so many physical signs and symptoms, is a psychical disease. They base their suppositions on observations of the attacks or fits, which, they declare, are expressions of extreme fear or anger giving rise to such violent attempts at flight or fight, with mental disorganisation and physical incoördination, that the patient is at once rendered unconscious and totally incapable of acting in a purposive manner. We are at liberty to accept this explanation provisionally, for many epileptics show no physical cause for their attacks. We must then turn our attention to the question of what constitutes mind, for the instinct to escape from or to fight a threatening danger, and the emotions of fear and anger which accompany its working, are mental activities.

The Evolution of Mind.

The "Mind" is that which minds the individual—i.e., takes heed or care of it. Mind is not a mysterious deity or spirit enthroned in the body, but the function of groups of specialised cells whose duty it is to govern and coördinate all the groups of cells comprising the body. A simple unicellular being, such as the amœba, has innate tendencies which cause it to behave, inevitably, in certain ways. It must be nourished, it must divide, and it must exert some resistance against environmental activities. Accepting the theory of the evolutional origin of multicellular beings, we can understand that in their simpler forms every cell possesses these tendencies, but that in more complex forms it is necessary for groups of cells to undertake certain functions in order to fulfil these essential needs. Some groups specialise in nutrition, others in reproduction, and others in defence. That all these groups may work together for the common good, it is necessary for them to be coördinated and directed, and this is the function of the nervous system. A coördinating and directing system must know something of the groups it has to govern, or "mind." Its duty is not to digest, to fight or to reproduce, but to mind these processes, and so we may assume that the functions or enduring processes

of the cells which do this work constitute the foundation of mind. The mind, therefore, is founded on the instincts of nutrition, self-protection and reproduction, which give rise in special situations to qualities of experience called emotions. Each instinct has its own peculiar emotion (which some believe sets it in motion and others believe results from its motion). The instinct of nutrition is associated with the experience of hunger, the instinct of self-protection with that of fear or anger, and the instinct of reproduction with love or lust. Instinct and emotion always work together in this way. Love never gives rise to anger and fight, hunger for food never arouses the reproductive instinct, and anger never activates the nutritional instinct.

In the higher animals the cells which perform these fundamental instinctive functions are believed to be in the basal ganglia of the brain. Therefore, just as there are areas of the brain which possess innate power to transform neuronic changes of special kinds into experiences of sensation—i.e., seeing, hearing, tasting, smelling, and touching, and experiences of physical movement, so there are areas in the basal ganglia which correlate all these changes into the experiences which we call emotions or feelings.

Effect of Neuronic Instability.

It is well understood that any neuronic instability results in disordered function. Neuronic instability anywhere in the visual system will give rise to defective sight or visual hallucinations. Neuronic instability in the auditory system will occasion defective hearing, manifested either in various degrees of deafness or in auditory hallucinations. The same is true of the tactile and other sensory systems, in which defective function or hallucination is by no means uncommon, and of the efferent nervous systems, whether secretory or motor. Instability of the secretory neurones will cause hypo- or hypersecretion, while instability of motor neurones may result in paresis, paralysis or twitchings, or clonic or tonic spasms of the muscles they innervate. It would not, therefore, be surprising to discover that instability of some of the neurones of the basal ganglia gave rise to emotional hallucinations.

Some writers on epilepsy have attributed the attacks to abnormal activity in the cortex of the cerebrum. When the cortex is known or found post mortem to be diseased or otherwise injured, the inference is reasonable, but it does not account for the fits. Disease and injury are by no means always followed by such severe disturbances, and in many epileptics no cause whatsoever is found for the fits. While the fits do not differ to any great extent, the auras and hallucinations do. Some patients experience gastric or other "sensations," some visual hallucinations, others auditory, tactile, or olfactory impressions, and a few have described "presences," desire to run, or a feeling of happiness. This would suggest, if we believe that the origin of the attacks is in the cortex: (1) that it is the cortex which enables all these varied activities to be experienced; and (2) that areas of the brain as widely separated as the cuneate and uncinate lobes are subject to the same form of malfunction. This may be so, but it would be more convincing to trace the tracts of those lobes to a point or area where they converge, and whence a disturbance might spread to any one of these areas and downward in such a way as to be widely effective. The basal ganglia of the diencephalon would satisfy this description. If they are the site of the lesion the premonitory experiences of the patients would depend on the proximity of specialised sensory neurones to the site of the disturbance, which of course would be constant though different in each individual. The spread of the disturbance, once it has begun, is rapid. Rushing upwards, it disorganises the higher functions of the brain and causes disassociation, which renders awareness of self and environment impossible; rushing downward over a wide area it gives rise to disorganised or incoördinated violent muscular activity. Head and Holmes have placed in the thalamus the origin not only of primitive emotional experiences but also of primitive sensory experiences. This is consonant with the facts in the majority of hallucinations of epileptics, and of all sufferers from night-terrors and migraine. Their hallucinations are primitive, and often lack the perceptional qualities of true senses, or of hallucinations of senses which might be supposed to originate in perceptual areas of the cortex.

On this assumption we can understand the psychologist's belief that an epileptic fit is an expression of horror, terror, or fury, but we cannot consider it to be a primary psychical disturbance, for we can indicate its area of origin and show it to be an hallucination of an emotion which is due to neuronic instability, probably in the thalamus and certainly in the basal ganglia. Dr. Shackle, in his note on night-terrors, said: "The sensation experienced can be but inadequately described as fear of the most paralysing and dreadful kind, no fear experienced in nightmares or real life having any relation to it whatsoever." Similar experiences have been related to the present writer in the same emphatic terms, and since some of the patients, though still the victims of these awful visitations, are no longer children, they are good witnesses. Like Dr. Shackle, they distinguish between the visual and intense emotional disturbances of nightmares and the pseudo-visions and emotional hallucinations of the night-terror. That the latter is due to neuronic disturbance in the areas of primitive sensation and emotion is probable.

The Cause of Neuronic Instability.

The basal ganglia have to govern the physical needs of the body—nutrition, self-protection, and reproduction. Government is performed largely through the autonomic nervous system and the endocrine system. The nutritional system is developed from the endoderm, the self-protective from the ectoderm, and the reproductive from the mesoderm, and from these tissues are developed the endocrine glands which work in conjunction with the autonomic nervous systems which govern them. Thus from the endodermal tissue, the anterior lobe of the hypophysis, the thyroids, parathyroids, thymus, and pancreas are budded off. Out of the ectoderm, which is devoted to self-protection, are developed the posterior lobe of the hypophysis, the chromaffin bodies, and the medulla of the suprarenal organs. The mesoderm is responsible for the gonads, which are developed with the cortex of the suprarenal organs—probably as a reproductive adjuvant—and the mesoderm system uses the endocrine organs of the other systems because its duty is to form the offspring which requires a moiety of them all. That the basal ganglia depend upon the secretions of the glands they govern for their anabolism—nutritive system—and for their katabolism—self-protective system—is probable. If this be so, then any neuronic instability in the basal ganglia may have its origin in one or other of these systems, and it is there we should look for the cause of night-terrors, epilepsy and migraine, if not of the psychoses also. These are, primarily, physical diseases, though argument might be used to show that abnormal and prolonged strain was the beginning of endocrine mal-function. To such an argument may be countered Adler's suggestion that the endocrine organs involved inherited a weakness, which, for the efficient fulfilment of their function, necessitated an over-compensation of the mind, which was thus exposed to undue impression and influence from environmental factors.

HOSPITAL COÖRDINATION IN NORTH STAFFORDSHIRE.—There are four important institutions in North Staffordshire serving a very large population—the Royal Infirmary, the Haywood Hospital, the Longton Cottage Hospital, and the Cripples' Aid Society. A committee of representatives of the four is considering the feasibility of a scheme of coördination, to be helped by a comprehensive contributory scheme. It is pointed out that, although the North Staffordshire Infirmary has recently added 42 beds, the provision of beds for the district is at present rather less than 1 per 1000, whereas it ought to be 3 per 1000.

Clinical and Laboratory Notes.

A CASE OF INTRACRANIAL HÆMORRHAGE FROM ARTERIAL MALFORMATION

By Bruce Maclean, M.D., M.R.C.P. Lond.,
CLINICAL ASSISTANT, NORTH STAFFORDSHIRE ROYAL INFIRMARY.

A FULL report on this type of hæmorrhage, under the name of Spontaneous Subarachnoid Hæmorrhage, has been given by Symonds,[1] who points out that the term "spontaneous" does not imply an absence of ascertainable cause but that it covers all cases of non-traumatic origin. As the presence of the blood in the subarachnoid space under these circumstances indicates either a primary hæmorrhage of the subarachnoid vessels or one that has found its way through cerebral tissue, we might, perhaps, allude to the condition as "intracranial." Further, in view of the description of the cause by Turnbull [2] as 'an inherent weakness due to a congenital abnormality in the structure of the arteries at their points of junction," it might be advisable to omit qualifying it as "spontaneous," and one can definitely exclude in the pathology such conditions as neoplasm, inflammation, infective endocarditis, blood and deficiency diseases. This case would appear worth recording on account of its rarity, inasmuch as death so delayed from an arterial source is very unusual.

The Case Described.

I was called in consultation to see a young man of previous good health, aged 29, a school teacher, who stated that while sitting downstairs he experienced a sensation as if something had burst in his head. He immediately rushed upstairs to seek assistance from his family, which he was able to do before collapsing on the bed. He had vomited before my arrival with relief. He looked pale and ill but was able, on effort, to discuss the events leading to the attack. Headache was severe and he resented interference. Examination revealed no typical signs usually associated with apoplexy (no palsies, rigidity, or abnormal reflexes), despite the fact that he had collapsed with temporary unconsciousness. The possibility of a sudden œdema of, or hæmorrhage into, a cerebral tumour came under review, as a warning against a lumbar puncture in the event of a fatal compression of the medulla from increased intracerebral tension. Any risk of syphilitic infection was emphatically denied. His father stated that they had partaken of "pork and beans" for supper, and that he himself had suffered nausea. A diagnosis of food poisoning was tentatively held.

The next morning I found him curled up in bed, but there was a general improvement, the outstanding symptoms being headache, pain behind his eyes, pain in the neck, lethargy, and a dislike of being disturbed. He was perfectly rational. Cramp was felt in both legs. Urine, pulse, temperature, blood pressure were normal. Re-examination of the nervous system revealed the following signs: Full flexion of the head was prevented by pain in the neck. On testing for Kernig's sign there was difficulty in producing complete extension at the knee. The left knee-jerk was more responsive than the right.

The exact diagnosis was puzzling, it being difficult to distinguish between food poisoning with meningismus from acute toxæmia, influenza with abdominal and encephalitic symptoms, and encephalitis lethargica. Cerebral tumour and meningitis from any cause could now be discarded owing to the sudden onset, absence of pyrexia, and general improvement. The possibility of intracranial hæmorrhage without any accompanying pathological state seemed to me remote. Agglutination reactions at the end of the week were negative to enteric and food poisoning bacilli.

Subsequent History and Post-mortem Finding.

The patient continued to improve daily, was out of bed in ten days and, on his own accord, returned to school a fortnight later. In four weeks from the commencement of his illness a similar attack developed, and although the lethargy was more marked, I am informed that the onset was comparatively slow, commencing with headache which drove him to bed. Confusion of thought developed to a slight extent next day, but all questions were answered rationally, and he gave a correct account of his previous attack. The following day he was admitted into the Leeds General Infirmary under Dr. Maxwell Telling, by whose kind permission I am able to supply the following information:—

"When first seen he presented nothing except a painful headache and a resentment of interference. After a little while the signs changed rather suddenly. He developed head retraction, squint, double Babinski sign, absent abdominal reflexes, Kernig's and Brudzinski's signs. As meningitis was suspected, especially as the headache was becoming intolerable, the cerebro-spinal fluid was liberated under greatly increased pressure, presenting a uniformly blood-stained appearance. Very little was allowed to escape. The hæmorrhage had been so severe as to cause coma and death the ensuing day. Post-mortem examination revealed around the meninges at the base altered blood, the result of an old extravasation. There was blood-clot of various ages, most of some standing, in the ventricles and in the floor of the skull. In the right frontal lobe was a mass of blood-clot with much old and new cerebral softening around it. The mass was fully the size of a large walnut. In the substance of the clot, and arising from the right anterior cerebral artery, could be demonstrated a ruptured aneurysm."

Commentary.

It would appear, therefore, that the original hæmorrhage had burst into the ventricles; this belief receives support from the age of the extravasation in the ventricles and the history of unconsciousness and vomiting at the onset. It is difficult to make this assertion in the face of the statement that "an intracerebral hæmorrhage sufficiently large to rupture into the ventricles or subarachnoid space would give rise to permanent cerebral damage (if such case ever recovers)."[1*] The aneurysm in this case probably arose at the bifurcation of the anterior cerebral and anterior communicating arteries; in this position it would be buried between the inner surfaces of the frontal lobes where there is absence of covering by arachnoid tissue. Consequently a rupture would force its way into the frontal lobes. It was afterwards ascertained that the patient was fond of athletics, being used to severe strain as a captain in tug-of-war teams, and I would contend that such excessive strain was a factor in developing his aneurysm at such an early age. It is quite possible for this structural defect to be of fairly common occurrence, and that, without severe exertion, would not give rise to aneurysm or rupture in the absence of arterial disease.

There is little reference to this subject in text-books on medicine, and it is questionable whether it should be confused with congenital aneurysms which are multiple, of small size, and situated chiefly on the circle of Willis, not necessarily favouring the junction of vessels. The favourite site of aneurysms resulting from defective arterial structure is at the fork formed by the anterior communicating and anterior cerebral arteries, and with few exceptions, post-mortem examination has revealed a single aneurysm. Cases arising in young people afford particular interest, and as the condition is not generally recognised in this country, there is bound to be great difficulty in its diagnostic interpretation. Obscure cases in the past have been ascribed to hæmorrhagic meningitis or encephalitis. On the continent a good deal of work has been devoted to its various clinical manifestations, and apart from seven cases recorded by Wilks in 1883, investigations were first published over here by Turnbull [2] in 1914, by Fearnsides [3] in 1916, and by Symonds [1**] in 1924. Associated with hæmorrhage into the subarachnoid cistern, characteristic changes in the cerebro-spinal fluid were described by Froin [4] in 1904. These may be summarised thus: There is increased pressure soon after the onset of hæmorrhage and the fluid contains blood. Specimens taken at intervals do not vary in the admixture of blood and cerebro-spinal fluid; they show no coagulum on standing, and the supernatant liquid is pink, brownish, or even yellow, according to the rate of hæmolysis. The last three features afford contrast

to those met with when dealing with accidental venous hæmorrhage arising during thecal puncture.

Diagnosis and Treatment.

The diagnosis can be simplified by recalling the following salient features: (1) Previous good health or history of a similar attack. (2) A sudden onset with outstanding symptoms of headache, collapse, lethargy, and pain in the back of the neck. (3) If conscious, the patient is rational. (4) Signs of (*a*) deep cerebral lesion, (*b*) cranial palsies, (*c*) meningeal irritation, (*d*) combination of (*a*), (*b*), and (*c*). (5) Absence of pyrexia in first few days. (6) In the absence of trauma the signs do not fit in with any other cerebral condition.

Confirmation of the diagnosis is obtained by carrying out intrathecal puncture, whereby the characteristic macroscopic appearances may be verified. An acute hæmorrhagic meningitis (including anthrax), might produce an even admixture of blood and cerebro-spinal fluid, but the presence of a fibrinous coagulum taken in conjunction with high temperature afford sufficient evidence.

I would allude also to three pathological conditions associated with "cerebro-meningeal hæmorrhage."

The first was originally described by Widal [5] as "*massive albuminuria*," which is present in a certain proportion of cases during the early stages of the illness and is transient in nature. It is evidently the outcome of shock and damage to the nervous system for the kidneys appear free from signs of disease post mortem, while I have found it present in other sudden cerebral disturbances, such as apoplexy and epilepsy. The second is *intra-ocular hæmorrhages* into the retina or vitreous, resulting from obstruction to the veins from the retina and optic nerve. Riddoch and Goulden [6] emphasise this clinical sign as the important diagnostic feature, but it has not been constantly witnessed by other observers.[7] [8] The third is *glycosuria*. This has been met with early in the attack, and is ascribed to reflex action from the controlling centres in the brain to the suprarenal cortex. The blood-sugar content is normal. The phenomenon may be correlated to the experiments carried out by Claude Bernard when glycosuria was produced by puncturing the floor of the fourth ventricle.

As regards treatment, it has been suggested that routine lumbar puncture should be performed in order to relieve the high pressure upon nervous tissue, but this procedure must first be carefully considered. The possibility of allowing the medulla to be forced down upon the foramen magnum on releasing the spinal pressure might easily invoke cessation of both respiration and heart beat. Further, a lowering of intrathecal tension might conceivably encourage bleeding from the site of rupture. One must be guided, therefore, by the severity of the symptoms indicating drainage for relief of pressure which is endangering life. Symonds states that "clinical evidence of intraventricular hæmorrhage should therefore be contra-indicated for this procedure, but that, later, it may be judiciously employed to relieve pain and to accelerate recovery." [1]

The prognosis must, of course, be uncertain; severe cases have been known to recover and remain in good health for years. Recurrence of symptoms is common, and any attack may prove fatal.

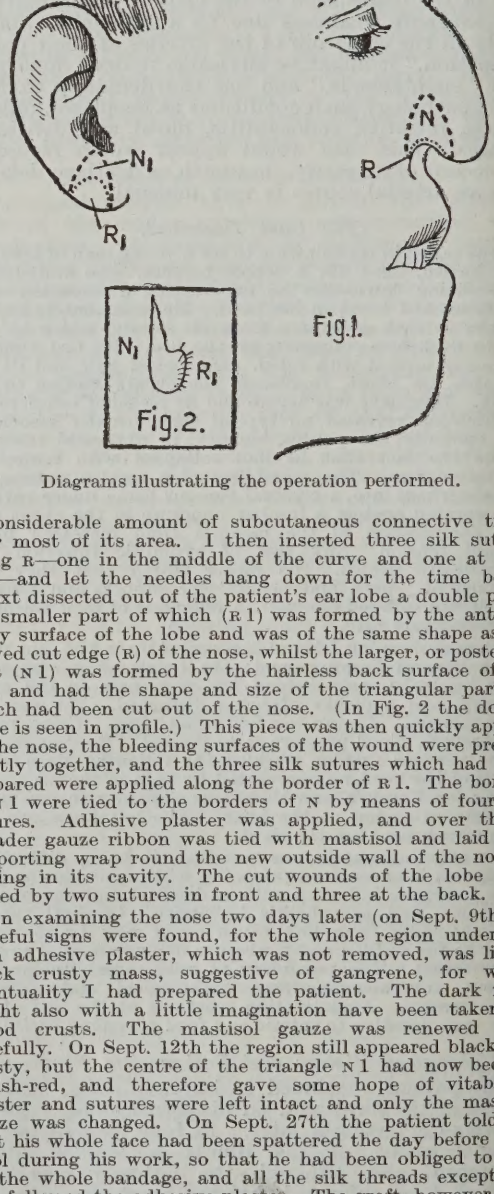
A NEW METHOD OF PARTIAL RHINOPLASTY.

By Dr. E. Dujardin,
COPENHAGEN.

In this method a triangular double piece of the lobus auriculi is applied so as to form one side of the nose and the outside wall of the nostril. The technique and treatment of the case were as follows.

The patient was a young farmer, 23 years of age, who at the age of 13 fell on the ice and injured his nose in such a way that a third of it, the tip and the outside walls of the nostrils, became gangrenous and fell off. In order to form an outside wall for the right nostril I proceeded as follows:—

After disinfecting by brushing with 5 per cent. thymol alcohol, and anæsthetising by novocaine-adrenalin, I cut off a thin skin margin along the lower curved border (see Fig. 1, R), as shown by the dotted line. Along the side of the remaining part of the nose I dissected off a triangular piece of skin (N), very thin towards the borders but retaining



Diagrams illustrating the operation performed.

a considerable amount of subcutaneous connective tissue over most of its area. I then inserted three silk sutures along R—one in the middle of the curve and one at each end—and let the needles hang down for the time being. I next dissected out of the patient's ear lobe a double piece, the smaller part of which (R 1) was formed by the anterior hairy surface of the lobe and was of the same shape as the curved cut edge (R) of the nose, whilst the larger, or posterior, part (N 1) was formed by the hairless back surface of the lobe and had the shape and size of the triangular part (N) which had been cut out of the nose. (In Fig. 2 the double piece is seen in profile.) This piece was then quickly applied to the nose, the bleeding surfaces of the wound were pressed tightly together, and the three silk sutures which had been prepared were applied along the border of R 1. The borders of N 1 were tied to the borders of N by means of four silk sutures. Adhesive plaster was applied, and over this a broader gauze ribbon was tied with mastisol and laid as a supporting wrap round the new outside wall of the nostril, ending in its cavity. The cut wounds of the lobe were joined by two sutures in front and three at the back.

On examining the nose two days later (on Sept. 9th) no hopeful signs were found, for the whole region under the thin adhesive plaster, which was not removed, was like a black crusty mass, suggestive of gangrene, for which eventuality I had prepared the patient. The dark mass might also with a little imagination have been taken for blood crusts. The mastisol gauze was renewed very carefully. On Sept. 12th the region still appeared black and crusty, but the centre of the triangle N 1 had now become bluish-red, and therefore gave some hope of vitability. Plaster and sutures were left intact and only the mastisol gauze was changed. On Sept. 27th the patient told me that his whole face had been spattered the day before with lysol during his work, so that he had been obliged to tear off the whole bandage, and all the silk threads except one had followed the adhesive plaster. The graft, however, had taken, and forms a fairly good passage from the nose to

the cheek, has a natural border covered with epidermis downwards, and is hairy on the surface towards the cavity of the nose.

The advantages of this method of partial rhinoplasty, which, I believe, has not been practised before, are the good cosmetic result and the possibility of operating under local anæsthesia without a subseqent Thiersch transplantation to cover the region from which the piece of skin has been taken. In the case referred to, the lobe of the ear healed pretty well. The patient himself thinks that his ear is improved; at any rate it is smaller.

A NOTE ON
THE IMMEDIATE REPAIR OF THE TORN PERINEUM UNDER LOCAL ANÆSTHESIA.

By F. J. Browne, M.D. Aberd., D.Sc., F.R.C.S. Edin.,

PROFESSOR OF OBSTETRIC MEDICINE, UNIVERSITY OF LONDON; DIRECTOR OF THE OBSTETRICAL UNIT, UNIVERSITY COLLEGE HOSPITAL, LONDON.

THE immediate repair of the perineum torn in labour often presents some difficulty in so far as anæsthesia is concerned, and the difficulty is naturally greater in general than in hospital practice, where all facilities for general anæsthesia are available. Without anæsthesia of some kind it is impossible to repair the perineum properly and with strict surgical asepsis. In University College Hospital we have for the past six months been using local anæsthesia entirely for this work and with such success that I feel the method should be generally known and used.

Technique.—The perineum is repaired only after the placenta has been expelled, as suture cannot be carried out or even the stitches nicely inserted before. The patient is put in the lithotomy position, the legs being supported, in private practice, by assistants or by a lithotomy strap of strong webbing, such as can be bought from most instrument makers. The operation area having been cleansed and draped in accordance with modern surgical requirements, the wound in the vagina is exposed from base to apex, together with its continuation in the perineal body. About 4 to 6 drachms of a 2 per cent. solution of novocaine are prepared and 1 minim of 1 in 1000 solution of adrenalin chloride is added for each drachm of the novocaine. A gauze swab soaked in this solution is laid on the raw surface of the wound while the syringe is being charged. An ordinary hypodermic syringe is used with a fairly long needle. In injecting the solution the needle is entered through the raw surface (by this time anæsthetised) immediately under the vaginal mucous membrane or skin of the perineal body. The needle is now carried horizontally outwards immediately underneath the skin (or mucous membrane when infiltrating the vagina) infiltrating as it penetrates so that a weal is formed, the skin overlying the needle becoming slightly œdematous. The infiltration is carried out on both sides at points about half an inch apart until both vagina and perineal body are treated. The injection itself causes no pain if the torn surface has been previously anæsthetised by the novocaine-soaked swab as above described. Suturing can then be proceeded with leisurely. Interrupted catgut sutures are inserted in the posterior vaginal wall, starting at the apex and working downwards. If the tear in the perineal body is at all deep it is better to insert three or four buried interrupted catgut sutures to the depth of the wound so as to bring together the levator ani muscles. Finally, four or five silkworm-gut sutures are inserted through the skin surface of the perineal body. These should take a wide bite on each side, should go deep to the deep surface of the wound so that no dead space is left, and they should not be tightly tied. Their ends are left long and knotted together. A sterile gauze dressing and vulval pad are then put on. While inserting the stitches it is better to ask someone to talk to the patient in order to distract her attention, thus getting good relaxation. The total quantity of novocaine solution used, including that taken up by the gauze swab, is about 4 to 6 drachms, depending on the extent of the tear.

After-treatment.—The patient is allowed to sit up in bed next day. After the bowels are emptied or urine passed, the vulva is sponged with 1 in 4000 solution of perchloride of mercury. No dusting-powder is used, and the patient is not douched. On the evening of the second day 2 tablespoonfuls of liquid paraffin are given; this is repeated in the morning and at noon of the third day, and on the evening of this day 1 oz. of castor oil is given. The bowels act on the morning of the fourth day, and no enema is required or given. On the tenth day the silkworm-gut stitches are removed.

No originality is claimed for the use of local anæsthesia in immediate perineal repair, but in several text-books of obstetrics consulted I can find no mention of it. The advantage of the method is that perfect anæsthesia and relaxation are obtained without the administration of a general anæsthetic with its attendant worry, risk, and subsequent vomiting and discomfort. Healing has been in all cases good.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

A MEETING of this Section was held on June 15th, Mr. Comyns Berkeley, the President, in the chair.

Prof. B. Stroganoff (Leningrad) communicated a paper, which was read by Mr. W. Gilliatt, on the

Standard of Results in the Treatment of Eclampsia.

Prof. Stroganoff began by quoting figures from various countries to prove that eclampsia was still one of the greatest dangers that might befall the child-bearing woman. In the United States 5000 women died of it annually and, while 6000 died of puerperal sepsis, it was unusual in these cases to lose the child as well. In eclampsia as many babies as mothers died, so that the total loss of life was much greater. Lees had stated that 25,000 women died annually in childbirth, and Moscher had estimated that one woman in every 1000 lost her life. Dr. Janet Campbell's figures for this country put the rate at 4·11 per 1000, or one in every 342. Improvement was in progress in Germany as the result of adopting the Stroganoff method (the removal of irritating influences, narcotics, and the maintenance of the functions of the kidneys, skin, lungs, and heart). Prof. Zweifel, of Vienna, had had a mortality of 8·5 per cent. in 316 cases, and Prof. Leopold had reduced his maternal mortality from 19 per cent. to 8 per cent. and the fœtal mortality from 55·7 per cent. to 18·6 per cent. Jacobs, using the prophylactic method, had only had three deaths in 48 cases; two had been moribund on admission and one had died of inflammation of the lungs. Not one of them had had a single fit after the beginning of treatment. In America Williams, at the Johns Hopkins Hospital, had reduced mortality from 22·8 per cent. to 13·3 per cent. Prof. Stroganoff's own figures for 360 cases showed a maternal mortality of 6·6 per cent. and a fœtal mortality of 21·6 per cent. In his opinion the prophylactic method, properly applied, should give a mortality-rate in eclampsia of between 1 and 2 per cent., or, if neglected and infected cases were included, of between 2·5 and 4 per cent. As yet no one had carried out the treatment in a sufficient number of cases. Some people had had bad results, but this was because the method was not used strictly or correctly. Altered régime meant impaired

results. A fixed scheme of administration of narcotics was no part of the method, and it was essential to vary the plan with the patient's condition. Where the results had been bad he had usually found a want of individuality.

Prof. Stroganoff's own most recent general mortality-rate was 2·6 per cent. Out of 300 cases eight had died, and in only one had it been impossible to control the convulsions. Her heart had been found post mortem to be permeated with fat, and, among other disabilities, she had had bronchitis, perisplenitis, chronic nephritis, and multiple hæmorrhages. The fœtal mortality was 6 per cent. In 40·3 per cent. of the 300 cases there had not been a single fit after commencing treatment, and only 15 per cent. had had four or more fits. No maternal deaths had been due to the treatment; on the other hand, 4 per cent. of mothers died after forced delivery. The operative deliveries had only been 50 per cent. Rapid recovery had been general. He analysed the eight deaths as follows: (1) Intractable hæmorrhage. (2) Two fits at home, eight in hospital. Forty-eight hours in labour, died of septicæmia. (3) Placenta removed manually and uterus ruptured. (4) One fit before admission and four after delivery; venesection, heart weak; fits controlled, died of double pneumonia. (5) Several fits at home, admitted comatose, stopped breathing under chloroform; four more fits, controlled, died two days later. (6) Sixteen fits at home, admitted moribund. Eclampsia came on after labour. (7) Two fits at home, deep coma, pulse-rate 110 and respiration-rate 40 on admission. No fits after admission, but went blue and died suddenly. (8) One fit at home and 11 in hospital, two after labour. Temperature 101·8, rising to 104; inflammation of the lungs and pleurisy.

Prof. Stroganoff then quoted a number of statistics from different countries to show the improvement since the adoption of his method. Eclampsia in hospital appeared to be more severe, but the results were more favourable. He considered that Cæsarean section often caused death and nearly always injured the patient unnecessarily. The prophylactic method was not ideal and could be improved; nevertheless its results were so much better than those of other methods that to many people they seemed unattainable. The quartz lamp was very important for the eclamptic patient. It involved no danger to the heart or nervous system and produced marked vasodilatation. While chloral hydrate could not be dispensed with, luminal or hedonal might be substituted for it after the fits had been controlled for eight or ten hours or where chloral was not absorbed. These two preparations had the advantage of not being dangerous to the heart and of being capable of administration subcutaneously or intravenously. There was some doubt whether chloral given rectally was absorbed. His opinion of magnesium sulphate was not favourable. About 20,000 lives were lost every year from eclampsia. The best results in this condition were achieved by the prophylactic method, but hardly anyone had used it strictly or fully. If they had, their results would have been better. The technique was very important and could only be learned by the bedside. Failing that, however the telephone consultation was a great help.

Discussion.

The PRESIDENT said that in this country it was not a fact that Prof. Stroganoff's results were unappreciated or that his treatment was untried. He (Prof. Stroganoff) had been most anxious that this paper should be read in order that the importance of the method might again be insisted on in the medical press.

Prof. FLEMING GOW spoke of conditions in India, where the obstetrician did not usually see his patient until she had had eight or ten fits and was comatose. The mortality was well over 20 per cent., but had decreased slightly since the adoption of a modified Stroganoff method. There seemed to be local variations. In Madras the usual method was venesection with Stroganoff; in Bengal, however, it was most unusual to find a blood pressure over 160, so that venesection was little used. Chloral hydrate was given in rectal saline. Cæsarean section for eclampsia had been abandoned, but was useful when eclampsia was complicated with the under-developed pelvis of the young primipara of 13 or 14.

Prof. MCILROY asked what Prof. Stroganoff's latest treatment was, and recalled that when he was in England there had been almost no cases of eclampsia for him to treat. He had ascribed the rarity of the condition to antenatal and prophylactic treatment. There ought to be a standardised form of treatment, Prof. McIlroy thought, particularly as eclampsia was largely treated by junior obstetricians. For about three years there had been no case of eclampsia at the Royal Free Hospital, and then a fulminating case had occurred. These must always turn up from time to time and provide a certain mortality.

Dr. E. H. ALTOUNYAN described the case of an Armenian girl of 18 who had failed to respond to chloral, venesection, and evacuation of the uterus, but who had benefited by intravenous administration of glucose, 300 g. in a 4·7 per cent. solution in distilled water. He had successfully repeated this treatment for a girl of 10 suffering from toxæmic nephritis after chicken-pox.

Mr. L. C. RIVETT said that the only case of eclampsia Prof. Stroganoff had found in London had been at Queen Charlotte's Hospital, where full record had been kept. Since then feeble efforts had been made to carry out his treatment, and it had been modified by every sister, every resident, and every member of the staff. In consequence the results could not be reported. At St. Mary's Hospital for the East End, however, Mr. Rivett had managed to keep his own modification unmodified and had had only three deaths in 44 cases. He endorsed Prof. McIlroy's plea for a uniform treatment. In answer to a question, he said that his modification included the use of chloroform.

Dr. DOROTHY LOGAN compared the value of glucose with the effect of cane sugar as a diuretic in certain cardiac cases, and asked for information about the excretion of chlorides. She cited a case where a patient who was under observation in hospital for another condition, and had developed eclampsia without any warning, despite the daily urine tests.

Mr. GILLIATT said that the chloride excretion was the basis of the anti-salt diet. He described a diabetic woman who became pregnant with twins. During her pregnancy she had required less insulin than before or after; apparently the pancreases of her babies were "doing their bit" for her. She had suddenly stopped excreting chlorides and almost "blew up" with enormous œdema, extending up to her waist. She had never had a fit nor albuminuria. Cæsarean section had been successful.

The PRESIDENT mentioned the successful results obtained at the Zürich Clinic, where Cæsarean section was performed directly the patient had the first fit.

Prof. LOUISE MCILROY reported a case of

Dysmenorrhœa due to Calcification of the Ovary.

The patient, aged 24, had suffered for a year from pain before, during, and after the period, lasting in all about a fortnight. She had consulted her doctor about a year ago because the pain was getting worse and the flow increasing. She had also suffered from dyspepsia. The menstrual pain was worse when she was sitting down than when she was moving about. All remedies had failed and a rectal examination had revealed a stony-hard tumour in the pelvis. The girl had looked perfectly well when seen by Prof. McIlroy. Operation had revealed a hard mass lying free in the pouch of Douglas with the tube forming its pedicle. Dark veins ran over its surface; it was too hard to cut, and X ray showed practically nothing. The patient's recovery had been uninterrupted, and she wrote this week that she had never had ache or pain since the operation, and had been married six months.

The PRESIDENT remarked that he had never seen a similar case, and asked why the pain had been worse whilst sitting down.—Prof. MCILROY replied that this was probably because the tumour was right down in the pouch of Douglas. She had not been able to find any similar cases in the literature.—Dr. F. E. TAYLOR

suggested that in such a young patient the tumour was more probably a degenerated dermoid than a fibroid.

Mr. CLIFFORD WHITE read a short communication on

Vulval Metastases from Pelvic Growths.

He said that it was of clinical importance to realise that metastases of the lowest part of the vagina might occur in cases of carcinoma of the uterus and ovary. In the cases he reported there was no question of gross involvement of the vaginal vault.

The first patient was a 7-para of 56 seen in December, 1926. Her menopause had taken place eight years before, and for four months she had had a blood-stained discharge. There was a tumour in the lower abdomen and what appeared to be a small papilloma in the vulva. After three weeks' treatment for diabetes she was operated on, and the right ovary was found to be 10 cm. in diameter, while the left was about 5 cm. Both were adherent to the uterus and intestine. The tumours and the body of the uterus were removed and no other foci were found in the abdomen. The nodule in the vaginal vault had by now increased in size to some 3×2 cm., and was raised and purple. It proved to be an adeno-carcinoma identical with that of the ovary. The patient died three months later.

The second case, a multipara of 70, was practically moribund when first seen. She had had abdominal pain and swelling and a blood-stained discharge. In addition to a semi-solid tumour and free fluid in the peritoneum she had a soft mauve nodule just inside the vulva. She died in a few days and no pathological material could be secured, but the clinical appearances were almost exactly like those of Case 1.

The third patient, seen in May, 1927, was a multipara of 40 who had had multiple uterine fibroids causing menorrhagia. She had had a panhysterectomy and a small adeno-carcinoma had been found in the body of the uterus after removal. She had been well until February of 1928, when she had noticed a pink discharge, and a pale purple, soft, raised growth identical with those of the two previous cases. The nodule proved to be a typical adeno-carcinoma like that of the uterus. The inguinal glands were excised and she was treated with deep X rays.

Mr. White said he had never met a case before the first of these three, and that their occurrence was difficult to explain. The literature recorded some secondary deposits of chorion epithelioma, but he had found no account of adeno-carcinomatous metastases. He would like to know if there was any anatomical explanation of their occurrence.

The PRESIDENT said he had seen cases of chorion epithelioma, but never cases like these.

Dr. CHRISTIE BROWN described three similar cases seen at the London Hospital. One was an adeno-carcinoma in a woman whose uterus had been removed for this form of growth 15 months before; two were secondary hypernephromata implanted just behind the urethra, possibly carried there by the urinary tract.

Reviews and Notices of Books.

THE NELSON LOOSE-LEAF LIVING SURGERY.

Edited by ALLEN O. WHIPPLE, M.D., Professor of Surgery, College of Physicians and Surgeons, Columbia University; Director of Surgical Service, Presbyterian Hospital, New York. Associate Editor, FORDYCE B. ST. JOHN, M.D., Professor of Surgery, College of Physicians and Surgeons, Columbia University, New York. Volumes I.–IV. New York: Thomas Nelson and Sons. 1928. $125 for complete set of 9 volumes.

BOOKS on surgery can be classified roughly into four types. There is the text-book which appeals to the undergraduate, the treatise for the general practitioner, the eclectic work of limited scope for the practitioner-surgeon, and, finally, the comprehensive system which strives to keep the consulting surgeon up to date, leaving out no methods or observations which have the slightest pretensions to consideration from the point of view of advancing science or art. The work under review belongs to the last class.

The task of compiling such a system must always be beset with endless difficulties, and very few works attain or maintain the standard set up by their editors. There is bound to be unevenness in the presentation of different branches of the subject when the services of numerous contributors must be requisitioned. It is high praise, therefore, to say that, judging from the first four volumes, this system of surgery bids fair to achieve very great success. There is not a single section that does not reach a high standard of effort, and the selection of authors has been admirable, the list including many of the greatest names in American surgery. How large the total number of contributors must be can be gauged from the fact that in these four volumes alone (there are to be eight in the completed work) more than 40 authors supply articles.

In Vol. I., physiology, pathology, bacteriology, and anæsthesia are discussed. Notable contributions are by J. E. Sweet on physiology, and by F. L. Meleney, who gives an account of the bacteriological and immunological aspects of surgery. Sweet's article is distinctive because of its clear and critical outlook, Meleney's because he brings to life a part of surgery which is often tedious to read about, by illustrating his statements with actual case histories. The names of J. T. Gwathmey and Gaston Labat as authors of the articles on general and local anæsthetic methods suffices to guarantee that these subjects are adequately dealt with. The arrangement of the matter in this volume, and indeed in the other volumes, is open to criticism; it is not always easy to find the actual information desired. For instance, there is no clear, full account of tetanus in any one place. Excessive subdivision on the one hand, and occasional sweeping generalisations on the other, must be accounted among the few drawbacks of this work. They complicate rather than simplify the presentation of surgery, especially when the services of so very many writers are involved. Thus, in Vol. II. appear articles on the surgery of tuberculosis and the surgery of malignant disease. In this country we do not think of surgery in such compartments; they do not seem natural divisions. Yet it must be admitted that one of the most interesting sections in the book is that by Ashhurst on the surgery of malignant disease, and the reader of this chapter may feel that there was justification for creating such a section. The chapter in this volume by Wilder Penfield on the principles of the pathology of neuro-surgery is exceptionally good, while G. H. Semken contributes an unusually clear account of the surgery of the neck. G. W. Crile, C. A. Elsberg, and B. Stookey also write in this volume.

Vol. III. contains orthopædic surgery, the surgery of the limbs and vascular system, and is less satisfactory than the rest. The orthopædic section particularly is sketchy, and practical details of some of the simpler orthopædic procedures are lacking. With regard to dislocations and fractures, from such a large treatise the reader expects help in real practical difficulties, and does not always get it. For instance, there is no description of the open operation for an unreduced dislocation of the shoulder, nor of one for habitual dislocation. In a special section on anæsthesia in the reduction of fractures local novocaine anæsthesia is extolled, but no description of how to apply this method is to be found. Spinal anæsthesia for leg fractures is not mentioned; perhaps the author thinks it too dangerous to be justifiable. Hugh Auchincloss's excellent article on the surgery of the hand is illustrated with a really splendid collection of drawings; it is marred only by one omission, the failure to tell us more about the restoration of function in the hand after septic infections, and the prognosis in these cases. An adequate account of amputations is supplied, but the chapters on varicose veins and osteomyelitis are not inspiring. There seems to be no mention of the injection treatment of varicose veins, and the reader has to turn

to Leriche's scholarly article on the vasomotor changes in blood-vessels to find an account of his method of treating varicose ulcers. It is interesting to read that Leriche has abandoned operations which remove sympathetic ganglia. Vol. IV. contains the surgery of the lymphatic system, the œsophagus, heart, pericardium, and hernia. In this volume we return to a uniformly high standard of achievement. The reader is not likely to search in vain for desired information in Torek's article on the œsophagus, or S. Erdman's article on hernia, whilst E. C. Cutler and C. S. Beck have written perhaps the fullest and most up-to-date account of heart surgery that exists.

The loose-leaf system has not only the great advantage of allowing new advances to be added from time to time, but it permits the revision of deficiencies which are bound to be present in any large book of composite authorship. If the remainder of this great work fulfils the promise of these earlier published parts, an extraordinarily reliable and satisfying treatise on present-day surgery will be at our disposal.

EPILEPSY.

By L. J. J. MUSKENS, M.D., Amsterdam. London: Baillière, Tindall and Cox. 1928. Pp. 435. 27*s.* 6*d.*

THE English edition of this book is not a mere translation, but has been prepared, revised, and brought up to date under the close supervision of the author by Mrs. W. Shaw Dunn. There can be few investigators as well-fitted as Dr. Muskens to write a book which embraces both the physiological and the clinical aspects of epilepsy. The volume under review is the fruit of many years devoted not only to the experimental study of convulsions, but also to clinical research upon epilepsy which began when the author was a pupil of Hughlings Jackson, Gowers, and Horsley. The result is a contribution to knowledge which, though distinctive in its outlook, is nevertheless in the direct line of the English tradition of neurology, and the fact that Sir Charles Sherrington has written a foreword is sufficient evidence of its importance from the physiological standpoint.

Part 1 of the book consists of an investigation of the fits induced in normal animals by convulsant drugs, especially by monobromide of camphor. It begins with a study of the "myoclonic reflex," which is the foundation-stone of the author's conception of the epileptic fit, and is the name given to a localised shock-like muscular contraction which occurs in a small proportion of normal cats in response to a tactile stimulus, such as an unexpected touch upon the skin of the back or a limb, or an acoustic stimulus such as a loud noise. Dr. Muskens found that monobromide of camphor enabled this reflex to be elicited in all cats, and that increasing doses of the drug caused: (1) a spread of the motor response so that all the muscles of the body might become involved, (2) a shortening of the refractory period, and (3) a tendency to after-discharge. Further, animals under the influence of this convulsant might exhibit spontaneous myoclonic movements which occurred in the absence of tactile and acoustic stimuli, and after sufficiently large doses they suffered from generalised epileptiform convulsions with loss of consciousness. These facts lead Dr. Muskens to take the view that the epileptic attack is the "central after-discharge" of a myoclonic reflex, which occurs when the maximal exaltation of the reflex is produced by a convulsant drug. In Part 2 the author describes the effect of experimental lesions of different parts of the nervous system upon the character of convulsions experimentally produced. Part 3 is devoted to epilepsy in man, ætiology, clinical features, and treatment being discussed. In dealing with human epilepsy Dr. Muskens naturally lays stress upon myoclonic epilepsy in its varied forms and the occurrence of myoclonic jerks from time to time in patients subject to major epileptic attacks, regarding these as phenomena which link epilepsy in man with experimental convulsions in animals.

The most important part of the book is the author's experimental work and the theory of the nature of epilepsy which he builds upon it. He has undoubtedly shown that a progressive heightening of reflex excitability precedes the development of the fits induced in animals by convulsant drugs, and is associated with a lowering of the threshold of different parts of the brain to faradic stimulation. This is a strong argument in favour of the theory that such convulsions are essentially widespread neural discharges; it does not necessarily follow, however, that the convulsion is of a reflex nature, a view which does not account for the associated loss of consciousness. Neither are the tonic elements of the epileptic fit covered by Dr. Muskens's theory; he proposes to regard these as a fusion of the clonic movements during their most explosive phase. He does not discuss the nature of the purely tonic fits (Hughlings Jackson's "cerebellar fits") which sometimes occur in man and which seem hardly explicable as a metamorphosis of myoclonic movements. Dr. Muskens has not escaped a further difficulty which besets all experimental investigators of epilepsy. Convulsions induced by drugs are certainly toxic and the view that the fit detoxicates the animal is permissible, though it may seem unduly teleological. But it is not justifiable to conclude without independent evidence, which has never been brought forward, that epileptic fits in man are also toxic in origin.

Many neurologists will consider that Dr. Muskens's physiological explanation of a convulsion is too simple and does not sufficiently take account of the complexity and multiformity of fits both in animals and in man. However, he has produced an outstanding contribution to the experimental study of epilepsy, and has submitted a sound and well-balanced discussion of its clinical aspects which is well worth reading.

A TEXT-BOOK OF BIOCHEMISTRY.

For Students of Medicine and Science. By A. T. CAMERON, M.A., D.Sc. Edin., F.I.C., F.R.S.C., Professor of Biochemistry, Faculty of Medicine, University of Manitoba. London: J. and A. Churchill. 1928. Pp. 462. 15*s.*

FEW English text-books have covered the same ground as this one by Prof. Cameron, which is worthy of attention. It is a well-packed volume of 450 pages, and deals adequately with the subject of biochemistry as a whole, and should be of great value to medical and physiological students. The first section consists of a well-written introduction and two chapters dealing with catalysis and pH respectively. In the second section there is a series of chapters on the biochemistry of the foodstuffs and their derivatives. The greater part of this is well-worn ground, and the author perpetuates one or two traditional errors that have appeared in text-books from time immemorial. For example, on p. 101 he states that "histidine is the only amino-acid to give a biuret reaction." We wonder how many of the people who have repeated this statement have actually tried the reaction. The third part of the book deals with the chemistry of digestion, the circulation, and the excreta. Then follows a long section devoted to intermediate metabolism, which, on the whole, is a very good summary of what is already known of this branch of the subject; the paragraph on insulin is rather disappointing. The fifth section contains two chapters, one on the chemistry of reproduction, and the other—a very short one—on the controlling agents of the metabolic processes. Section VI., on quantitative metabolism, includes descriptions and photographs of the Russell Sage calorimeter for the accurate estimation of basal metabolism. There is also a more adequate chapter on diet than is usually found in a text-book of this description. The author has included a few chapters

on "borderline subjects" in the last section, in an attempt to "break down the watertight compartments of the modern sciences." These have proved of particular interest and add considerably to the value of the book.

Prof. Cameron writes well, giving a clear idea of the scope and aims of biochemistry, and at the same time as much detailed and technical information as is necessary for the student. Trouble has been taken to make clear the meanings and sources of some of the very technical terms. Such an excellent book well deserves the success which Prof. Swale Vincent, in a foreword, desires for it.

ACUTE ABDOMINAL DISEASE.

Clinical Researches in Acute Abdominal Disease. Second edition. By ZACHARY COPE, F.R.C.S. Eng. Senior Surgeon to Out-patients, St. Mary's Hospital. London: Humphrey Milford, Oxford University Press. 1927. Pp. 214. 10*s.* 6*d.*

THE fact that this volume has so soon required a second edition is evidence of the interest it has aroused. It consists of a series of short articles on various points connected with acute abdominal disease. They are all original and valuable for their practical suggestions. Of the new chapters which appear in this edition, those on extravasation of bile and on shock are of the greatest interest. Surgeons may not agree with the author's views on shock, but they will appreciate the importance of the author's suggestions for its prevention and relief. The book should be studied by all who may have to deal with acute abdominal emergencies.

TRAVAUX ET MÉMOIRES.

Tome deuxième. By PIERRE MARIE. Paris: Masson et Cie. 1928. Pp. 393. Fr.30.

THE second volume of Prof. Pierre Marie's reprinted contributions contains his work on the Charcot-Marie variety of amyotrophy, on hereditary cerebellar ataxia and cerebral lacunes, and on more than 40 other topics of neurological and general interest. Those in all countries who have been pupils of this master of neurology, or who have followed his clinicopathological method, will welcome the chance of possessing in book form his opera omnia, which cover a period of 40 years and more, couched in a scientific language of conspicuous clarity, and representing an abiding addition to neurological learning such as few have ever equalled.

POSTURAL REFLEXES IN MAN.

Die Lagereflexe des Menschen. By HANS HOFF and PAUL SCHILDER, Psychiatric-Neurological Clinic, University of Vienna. Vienna: Julius Springer. With 20 illustrations. Pp. 182. R.M.12.

THE impetus given to clinical neurology by the physiological work of the late Prof. Magnus and his collaborators is having its effect in the output of clinical researches dealing with postural and correcting (or righting) reflexes as seen in man in normal and diseased states. To this study the slender monograph of Dr. Hoff and Prof. Schiller forms an appropriate contribution. They have made a special investigation of such reflexes in normal persons at different ages (infants, juveniles, adults), and have occupied themselves with the behaviour of these reflex reactions in various clinical conditions (cerebellar lesions, chorea, tabes, athetosis, hemiplegia, Parkinson's disease, epilepsy, the psychoses, and so forth). Several of their clinical tests are ingenious and may be new to English neurologists; at the same time it is evident that the application of the whole range of test reactions to some at least of the cases here described is comparatively useless. The authors seem themselves to be aware of this from their frank admission that a given reflex reaction has in such and such a case "no practical significance." Other investigations in their series contain no novelty and constitute merely an elaboration of some accepted phenomena, for example, those which bring out the physiological disorder of cerebellar disease. A summary at the end of the brochure deals in tabular fashion with some 20 types of reaction, subjected to painstaking scrutiny. A detailed criticism of the findings in the various nervous conditions already mentioned would lead to a highly technical discussion; we may, however, admit the observational value of the author's work without assenting to their interpretation of it in terms of Magnus and de Kleijn reflexes.

ACUTE APLASTIC ANÆMIA.

By A. HAYES SMITH. London: H. K. Lewis and Co. 1928. Pp. 80. 6*s.*

THIS book contains a detailed account of a case of aplastic anæmia with recovery occurring in a child aged 2 years. Numerous therapeutic products of one sort and another were used in the treatment, including a preparation of liver for subcutaneous injection. The author attributes recovery to this last, and therefrom deduces the existence of a liver "hormone" having an influence upon the bone-marrow. In the light of recent experience few will be found to quarrel with this conclusion, but the steps by which the author attains it are open to criticism. He quotes from the literature two further cases of aplastic anæmia in children in which recovery occurred without the use of liver. It is the experience of most of those who have had occasion to deal with this condition since liver therapy for pernicious anæmia came into vogue that it exercises no influence upon the course of anæmia of this type.

FRACTURES AND DISLOCATIONS.

Fracturen und Luxationen. Ein Kurzgefasstes Lehrbuch für Ärzte und Studierende von Dr. Med. K. H. BAUER, A.O. Professor für Chirurgie an der Universität Göttingen. Berlin: Julius Springer. 1927. With 237 illustrations. Pp. 236. R.M.16.80.

THIS book, as its title implies, is a manual for students and practitioners and makes no pretension to any extensive exposition of the subject. The pathology of lesions bulks larger than the treatment, but the therapeutic measures recommended are sound and, generally speaking, are within the reach of the general practitioner. The illustrations are good and clear. Figs. 208 and 209, which purport to represent the walking splint of Bruns, are really representations of Thomas's knee-splint and patten. The section on operative treatment of fractures is very meagre. Tongs extension is recommended, but the methods of Lane, Hey Groves, Delbet, and Albee are ignored, probably because they require operative facilities not often within the reach of a general practitioner. Dr. Bauer is still impressed by fear of pneumonia and other troubles which were formerly the bugbear of the surgeon who had to treat fractured femur in the elderly, although up-to-date surgeons such as Delbet keep their cases of fracture of the neck of the femur recumbent for three months and are able to record an almost negligible mortality.

MEDICAL TUBERCULOSIS IN INFANCY.

La Tuberculose Médicale de l'Enfance. By M. PÉHU and A. DUFOURT. Paris: Gastoin Doin and Cie. 1927. Pp. 732. Fr.75.

Drs. Péhu and Dufourt have produced an excellent volume on the tuberculosis of infancy from the point of view of the physician. No attempt is made to deal with surgical tuberculosis. The book covers a wide range and attention is paid to those details which the practitioner needs so much but does not always get in text-books. The information given is well up-to-date; even the new filtrable virus work being briefly described. Social hygiene and

preventive measures which form a very large part of the study of infantile tuberculosis, are fully dealt with, such efforts as the Graucher system being clearly described. The clinical pathology in the book is disappointing and the information given on treatment is not as full as it might be. An appendix of illustrative X ray plates is given, the index is good, and bibliography will satisfy the research student. No illustrations are given in the text. On the whole, this is a welcome relief; books on tuberculosis, as a rule, are overweighted by the large number of uninspiring reproductions of apparatus which convey little to the reader. We can recommend this book as a piece of conscientious work. It is written clearly and logically and is a model of condensation.

PRINCIPLES OF BACTERIOLOGY.

By A. A. EISENBERG. Fourth edition. London: Henry Kimpton. 1928. Pp. 228, with 40 text figures. 10*s.* 6*d.*

THIS excellent book would be better called "Elements" than "Principles"; it is a guide across the threshold of bacteriology and has nothing to do with the general propositions to which that science may ultimately reduce itself. It has been written, primarily, for use in training schools for nurses in the United States; and devotes a good deal of space to practical details, contemplating the possibility (already we believe to some extent realised in practice) that nurses may also function as laboratory assistants. Whether it will be of value for the same purpose in the more conservative English schools is perhaps open to question, but it is a good introduction to practical medical bacteriology for laboratory attendants, elementary students and anyone else who wants to get some knowledge of the subject, and is prepared to take a little trouble about it.

PHARMACOTHERAPEUTICS.

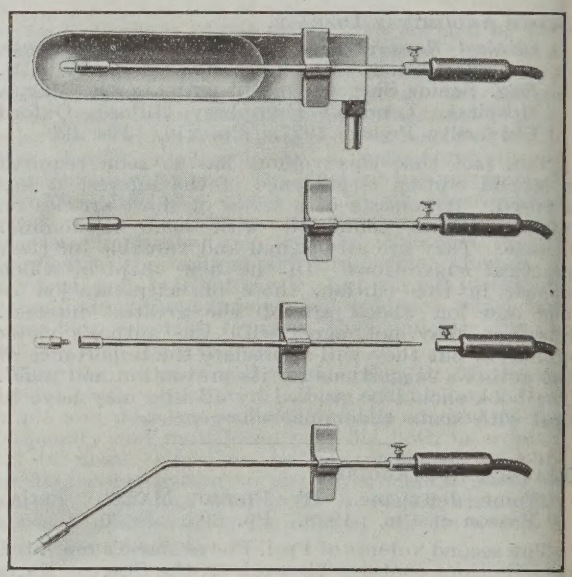
By S. SOLIS-COHEN, M.D., and T. S. GITHENS, M.D. London and New York: D. Appleton and Co. 1928. Pp. 2009. 63*s.*

THE first 400 pages of this book are given up to such subjects as drug influence, assay, and the sources and preparation of drugs. Valuable chapters are included on prognostic indications, symptomatic indications, absorption, elimination, and incompatibility. Under the heading of "Schools of Medicine" we are told the theory and practice of homœopathy, eclecticism, and dosimetry. The remaining 1600 pages are devoted to a systematic description of groups of drugs. Under each heading the history, chemistry, materia medica, therapeutics, and toxic action of the drug concerned are discussed. The authors have been most thorough and are well up to date. For example, a critical discussion of the use of such drugs as quinidine sulphate and phenylhydrazine hydrochloride is included, and also the value of non-specific protein therapy and the scarlet fever immunity test. The new work on the parathyroid and ovarian hormones is set out, and the photo-synthesis of vitamin D, which was not achieved until after the book went to press, is anticipated. Some confusion is caused by the difference in terminology of the U.S. or the British Pharmacopœias. Thus liquor arsenicalis (B.P.) becomes liquor potassii arsenitis (U.S.X.), and we find two entirely distinct preparations known as liquor arsenicalis pearsonii and liquor arsenicalis clemens. It is surprising that the leech should be so curtly dismissed by authors who define the rational method of therapeutics as "The giving of the right drug to the right patient in the right dose, and the right way at the right time." The British reader will be irritated by some of the expressions used, such as "nerve booster," but will appreciate the value of the book as a whole. It is very well indexed, and our only criticism of the production concerns the poor quality of the paper used.

New Inventions.

ILLUMINATORS FOR OPERATIVE RADIUM WORK.

A CLEAR operative field being of considerable importance in those operations of access which have as their object the exposure of deep-seated tumours for the insertion of radium, demands in many cases special means of illumination. To facilitate this, a series of illuminators (see figure) has been designed.



The construction of these permits of their attachment to speculæ, retractors, &c., used in the surgery of access, and to special vaginal speculæ used in the treatment of cancer of the cervix. Each carries a detachable lamp, while the current (4 volts) is conducted by means of a cord, detachable as shown.

The instruments are made by the Medical Supply Association, 167, Gray's Inn-road, London, W.C.

A NEW DRAINAGE-TUBING.

THE modification of drainage-tubing here illustrated consists simply of a solid rib (R) of rubber on opposite sides of the tube, to enable a stitch to be passed through without puncturing the lumen. De Pezzer tubes, indeed any kind of rubber-tubing used for drainage, could be easily treated in the same way. When a tube draining a jejunostomy, a cæcostomy, or a urinary bladder is anchored by a stitch, there is often a little leakage through the puncture, which tends to grow larger by tension. The escape of even a small quantity of fluid from the small bowel, a septic gall-bladder, or a severely infected urinary bladder, often causes a troublesome dermatitis and infection of the rest of the wound. This modification to the tube is designed to obviate such troubles. The tubing may be obtained from Messrs. Chas. Thackray and Co., of Leeds.

THE LANCET.

LONDON: SATURDAY, JUNE 23, 1928.

MEDICAL CARE OF SCHOOL-CHILDREN.

AMONG the real social advances of the present century in this country the concerted national effort for making a scientific study of children during the growing age is one of the most important. Although only the fringe of the net enveloping and hiding the factors of healthy growth has so far been touched, yet we already see, in the enhanced cleanliness, well-being, and physique of our children much encouragement for still further attempts to solve the difficulties inherent in the problems of life. But if no country in the world can show such an extensive and coördinated scheme of school medical service and of child welfare generally as exists with us, we must not forget that many gaps and anomalies are still apparent in that scheme, a position which was revealed in the recent debate in the House of Commons when the House went into Committee of Supply on a vote for £26,215,828 for salaries and expenses of the Board of Education. Mr. TREVELYAN, in moving to reduce the vote by £100, said that although the value of nursery schools so clearly shown in Sir GEORGE NEWMAN'S 1926 report was fully recognised by all, yet there were at present only 26 of these schools with a population of 1367 children out of 2,000,000 children between 3 and 6 years of age. Other speakers followed, pointing out that public opinion was now ripe to support the Board in giving a lead to local authorities for a favourable consideration of any proposals for the extension of these schools. In proof of the practical work done by the schools Viscountess ASTOR said that the average proportion of children entering them at 2 years of age, who were rickety, was from 80 per cent. to 90 per cent., but that within one year all cases of rickets were cured in the open-air régime of the nursery school. She added that the average proportion of the diseased and delicate entering elementary schools at the age of 5 years was from 30 per cent. to 40 per cent., while the average proportion of children who had attended a nursery school between 2 and 5 years of age was 7 per cent. The debate led to an expression of opinion from Lord EUSTACE PERCY, President of the Board, as to the relative merits, in dealing with malnutrition, of the giving of school meals only on medical certificate rather than merely giving a midday meal to all children whose parents were necessitous. His view was that malnutrition was a medical question and should be kept on that basis. The Duchess of ATHOLL, Parliamentary Secretary to the Board, defended the disallowance of the travelling expenses of school-children between the buildings and the playing-fields on what may be considered an exactly opposite view; for if the Board consider that money should be spent on general facilities which would provide opportunities for the children in schools rather than upon providing travelling expenses for individual children, the decision exactly cuts across the basic medical view that treatment—and athletics constitute treatment—should be directed to the places where it is required individually.

There is no longer dissociation between education and child hygiene; the balance between educational needs and the physiological demand for movement and play in children is being adjusted, and already in most places an organiser of physical training is working hand-in-hand with the school medical officer. The cost of apparatus for athletic and remedial exercises is already part of the educational outlay, but space for recreation is sadly lacking in most large towns, though such voluntary efforts as those of the Playing Fields Association are now producing good results. But the demand for playing grounds far exceeds the supply. It is, too, in just those areas where recreational facilities are most needed that they are lacking, and the children in such areas cannot afford the expense of travelling nor can this expense be incurred by the local authority. While the competitive spirit is necessary to stimulate interest and endeavour, it is not the outstanding performers who travel to the playing-fields; a whole class goes at a time, and those most competent to judge are unanimously of the belief that the mental, moral, and physical results more than justify the small expense of travelling. More playing-fields and more nursery schools are clearly needed. The activities of the nursery school are medical, social, and educational and aim to provide the right environment for the proper development of very young children. Sir GEORGE NEWMAN says: "The remarkable improvement in the health and nutrition of children attending nursery schools may be attributed to medical supervision, a suitable dietary, sufficient rest, and an open-air régime." For the most part children are selected for nursery schools either on social or medical grounds, so that the incidence of defects are heaviest on such children. Lady ASTOR'S figures of 80 per cent. to 90 per cent. of rickety children entering such schools appear to be high, and sufficient statistics are not yet available for proof of them; it is, however, true that rickets does disappear from the children attending those schools. Moreover, those children are of the age when many observers hold that infective conditions such as tuberculosis and rheumatism take root, and it might well be that the additional nurture provided can lessen or prevent much of the present incidence of these diseases. The nursery school age embraces those years of early character formation which may mould the ultimate personality for better or for worse; it also bridges the gap that now exists between the maternity and child welfare scheme and the school medical service—a gap the results of which has brought home the truth of the oft-repeated remark of Dr. C. J. THOMAS, senior medical officer of the London County Council, that "The school service is a receiver of damaged goods."

The difficulties in the way of establishing nursery schools are numerous and real. At present the public health authority is responsible for the maternity and child welfare scheme, and although coördination between the sanitary authority and the school medical service is in most places close many financial and administrative difficulties are ready to hand. Nursery schools are essentially expensive, partly because of the cost of premises and partly because of the necessary staffing, equipment, and management, including meals. Many mothers at present object to leaving their infants at a school all day. The question whether all the helpers should be certificated teachers is much debated, and yet there must be adequate guarantee of the status of people who train children. Few of these obstacles are insurmountable and coördination is becoming more real day by day. Already in many areas pre-school children are treated at the school clinics, for school experience has shown that the heaviest burden is the disease that springs from early childhood. The money spent in rectifying early evils will ultimately lessen the heavy costs for maintenance of hospitals, sanatoriums,

clinics, and other institutions for the treatment of disease. A simple beginning could be made by extending existing welfare centres, crêches, and day nurseries, and there are many highly competent women able and willing to superintend, direct, or assist in the management of such institutions, designed in the first instance to meet the needs of the physical and social welfare of the child. Children so prepared might then attend an elementary school at an earlier age than the usual school entrant age of 5 years. At the present time the giving of school meals is largely left to the discretion of local education authorities, and practice varies widely in different localities. The question of feeding necessitous children is one for the community as a whole to solve, but confusion is apt to arise, and often does arise, from the ambiguous use of what should be specific terms. Malnutrition is a pathological condition and may be the result of many physiological and pathological conditions besides insufficient or unsuitable diet. A necessitous child is not necessarily an ill-nourished child, just as a child suffering from malnutrition is not necessarily a necessitous child. The diagnosis of the cause and the treatment of malnutrition is essentially a medical question the elucidation of which calls for much skilled knowledge. Nothing but good can come from the focusing of public attention on the health of the children; it is of paramount importance in social and national life, and its preservation and improvement forms one of our greatest medical responsibilities.

THE PROBLEM OF THE PYLORUS.

ELSEWHERE in this issue we publish the third of the Croonian Lectures lately delivered before the Royal College of Physicians by Dr. CHARLES BOLTON. Those which have already appeared [1] contain a close analysis of the symptoms complained of by a group of 1000 persons seeking relief on account of pain coming on in relation to food, and it will have been noted that Dr. BOLTON recognises three syndromes, the pyloric, the cardiac, and the œsophageal, each of which he further subdivides. The third lecture is largely devoted to a detailed examination of the factors and mechanisms and effects of pyloric dysfunction. Of late years, physicians especially interested in gastric disease have more and more subscribed to the doctrine that spasm of the pylorus and the pyloric vestibule is the main factor in the production of delayed pain after meals, and Dr. BOLTON here sets out fully the facts on which this belief is based. The movements of the pylorus are governed by the myenteric plexus, and the sphincter undoubtedly reacts to solids and to strong acids in such a way that these cannot leave the stomach until reduced to a form more acceptable to the small intestine. Being controlled by a nerve-plexus the sphincter is further liable to reflex influences such as those from a diseased appendix or colon, whilst instability of the central nervous system will also tend to cause disorderly action in this region. Perhaps, however, the most interesting part of Dr. BOLTON'S lecture is the section where he discusses the influence of the pylorus as a regulator of the acidity of the gastric contents.

When investigating the case of Alexis St. Martin, BEAUMONT noted that bile was often to be found in the stomach, but it was not until BOLDYREFF demonstrated the presence of trypsin and the general regurgitation of duodenal contents in dogs that the importance of its presence was realised. BOLDYREFF was the first to point out that regurgitation from the duodenum to some extent neutralises the acidity of the gastric contents, so as to secure an optimal acidity for digestion in the stomach, and so as to protect the intestine against the effects of strong hydrochloric acid. When the fractional method of gastric analysis was introduced by REHFUSS, he and his co-workers confirmed the fact that trypsin is often present in the stomach, and BENNETT and RYLE, in the well-known work in which they established the types of acidity found in normal subjects, were at pains to explain the importance of this mechanism of regurgitation in the process by which the concentration of acid falls considerably during the later stages of digestion. In 1921 GOODHART and BOLTON, by an ingenious method of studying the various chloride constituents of the stomach contents, were able to demonstrate that, as the acid curve went up, the neutral chloride curve remained low, and that, as the percentage of acid fell, that of neutral chloride increased pari passu, the total chloride curve remaining unaffected. From these and other observations they concluded that the curve which really demonstrates the secretion of acid during the fractional test-meal is not the ordinary acid curve obtained by titration, but is rather the total chloride curve; the so-called acid curve really represents the progress of neutralisation. Their results have been confirmed by BAIRD, CAMPBELL, and HERN, as well as by ROBERTS and others, and in his present lecture Dr. BOLTON gives a full résumé of the evidence together with other data which go to support the hypothesis that regurgitation of the duodenal contents is a most important factor in the normal physiology of the stomach. Among the confirmatory evidence must be mentioned the work of R. W. A. SALMOND,[2] who by careful study of barium meals, has found that 93 per cent. of normal persons exhibit some degree of antiperistalsis of the duodenum. By this process the duodenal cap is often seen to be filled under pressure not only by the stomach but also by the duodenum, and when this happens at a time of pyloric relaxation, regurgitation into the stomach occurs. Dr. BOLTON believes that in the early stage of digestion the pylorus relaxes only before gastric peristaltic waves, and that as digestion proceeds and the acidity attains its normal height, the pylorus begins to relax independently of peristalsis; if the cap is filled at this time, the duodenal contents pass back into the stomach. In a later series of observations SALMOND has introduced a different type of regurgitation which occurs during both the passive and the active phase of the cap. While the cap remains distended, and between peristaltic waves, a trickle of barium may be seen to run back into the stomach, whilst at other times a contraction of the distal end of the cap causes the regurgitation. These radiographic findings are almost impossible to demonstrate except by direct observation, but it is to be hoped that X-ray cinematography will, in time, convince all who are interested.

While accepting duodenal regurgitation as probably the most important of all factors regulating the stomach's acidity, we must admit there are other possible factors. Thus PAVLOV regarded the gastric acid as being secreted at a constant level of concentration, the apparent variation being due to dilution of the early secretion of the body of the meal and partial neutralisation by the alkaline mucous secretion of the glands of the pyloric antrum; FOSTER and others have shown that in the presence of pepsin gastric mucus can neutralise a fairly large amount of

[1] THE LANCET, June 9th, p. 1159, and June 16th, p. 1211.

[2] Ibid., 1927, i., 1230.

acid. A third possible mechanism depends on the capacity of the gastric mucosa to secrete a diluting fluid. Thus ROTH and STRAUSS showed that the concentration of salt solution in considerable quantities could be reduced in 20 minutes from 2·8 to 1·7 per cent. They found that some new fluid must have been added because sulphate and phosphate were present in the gastric contents after the operation had taken place. BENNETT and CROHN have shown how strong solutions of glucose, of acid, or alkali are similarly diluted whilst lying in the stomach. It is too early to state which, if any, of these three factors is all-important, but BOLTON and his co-workers have certainly added very considerably to our knowledge by the confirmation of BOLDYREFF'S work, so ably summarised in the lecture we publish to-day.

THE TREATMENT OF ECLAMPSIA.

THE literature of eclampsia is an unwieldy collection of conflicting views. There are probably few diseases in which the observations of reputable workers have been so vehemently denied by other workers of equal standing. The reason for such acute dissension may be that, although convulsions associated with pregnancy are known by a common name, the pathological processes leading up to the fits are not the same in all cases. No satisfactory theory of their origin has yet been formulated and the ætiology of eclampsia remains obscure. The scheme of eliminative treatment devised by Dr. HASTINGS TWEEDY has been adopted as an empirical measure by many obstetricians who do not accept the theory of toxæmia on which it is founded; similarly, the removal of sources of irritation, and the exhibition of narcotics as practised by Prof. B. STROGANOFF, has been tried with good results, though the basis of this treatment remains hypothetical. Prof. STROGANOFF holds that eclampsia is of placental origin, being the product of two factors—the toxins circulating in the maternal blood, and the irritability of the pregnant woman's nervous system. The Dublin school believe that during the metabolic processes normal to pregnancy, toxins may accumulate owing to faults in management or deficient reserve power of the excretory organs. According to them, if toxæmia in the early stages is treated by starvation and laxatives, and the patient is encouraged to drink large quantities of water, eclampsia may be prevented. In the stage of convulsions their treatment consists of drastic purgation, lavage of the stomach and colon, and the promotion of diaphoresis and diuresis. The exact ritual of this school is familiar to readers of our series of articles on Modern Technique in Treatment.[1]

Prof. STROGANOFF, who is tireless in advocating the method which has been so successful in his hands, complained, in a communication submitted on June 15th to a meeting at the Royal Society of Medicine (see p. 1281), that its details are sometimes modified with unfortunate results. The main principles of his treatment are that the patient should be kept perfectly quiet in an isolated and darkened room; morphia should be given sparingly, choral hydrate in considerable quantities. All manipulations must be carried out under chloroform anæsthesia. Most careful attention to details is, however, essential if the best results are to be obtained. When the procedure advocated by him is minutely followed, and if the patient is not in labour, he claims that the fits generally cease and the pregnancy continues without reappearance of the symptoms. Prof. STROGANOFF does, however, allow certain modifications of the improved technique set out in THE LANCET in 1924 (vol. ii., p. 62). He approves of the substitution of luminal and hedonal for chloral hydrate in certain circumstances, their advantage being that they can be administered subcutaneously, whereas the only way in which chloral can be given to an unconscious patient is per rectum, when it may not be absorbed.

That conservative methods of treatment should be preferred to Cæsarean section or accouchement forcé was the definite conclusion reached by the sub-committee of the Section of Obstetrics and Gynæcology of the Royal Society of Medicine, appointed in 1921 to investigate the matter, and this conclusion was confirmed by reports from other societies received at the British Congress of Obstetrics and Gynæcology, held at Liverpool in 1922. But as between the techniques elaborated in Dublin or in Leningrad no pronouncement was made either by the committee or at the Congress. At the meeting of the British Medical Association held at Glasgow in 1923 the discussion favoured the Dublin procedure, but this was before the publication in this country of Prof. STROGANOFF'S improved prophylactic method. This has since been tried at Queen Mary's Hospital by Mr. L. C. RIVETT, who has treated 44 cases with only three deaths. In America, where conservative methods do not appear to have been generally accepted, JOHN WHITRIDGE WILLIAMS, at the Johns Hopkins Hospital, is said to have reduced his mortality from 22·8 to 13·3 per cent. by using this method, while Prof. STROGANOFF'S own recent figures are as low as 2·6 per cent. in 300 cases. It is to obstetricians working in this country, however, that practitioners will turn for more specific advice than they have hitherto received. The disease was never so common that the practitioner could hope to test for himself the different methods of treatment, and in recent years the increased number of women receiving antenatal care has further diminished its incidence. It is the more important that guidance should be available for the medical man who sees perhaps only one case in the course of five years. Assuming that conservative treatment is desirable should he adopt the Dublin method or that of Prof. STROGANOFF? The Section of Obstetrics and Gynæcology of the Royal Society of Medicine has recently drawn up a scheme under which reports from maternity hospitals will be issued on a definite pattern. Under this scheme the results at different hospitals should be easy to ascertain, and more valuable statistics, based on larger numbers, should be collected. The exact methods now used respectively by Dublin workers and by Prof. STROGANOFF could be tried on a considerable scale if all the maternity hospitals would coöperate to this end, and we suggest that a serious attempt should be made to decide which gives the better results under comparable conditions.

[1] THE LANCET, 1923, ii., 666.

LIVERPOOL AMBULANCE SERVICE.—The Voluntary Hospitals' Council of Liverpool is considering the best means of providing an ambulance service for transporting incapacitated patients from their homes to the hospitals. The work is at present performed by the police and privately owned ambulances, but it is felt that in the interests of the outlying districts a properly equipped service under the control of the Council has become necessary.

Annotations.

"Ne quid nimis."

POST-VACCINAL ENCEPHALITIS.

THE increase in cases of acute disease of the central nervous system during the last 25 years has been a notable feature of medical records. Epidemics of cerebro-spinal fever on the Continent, in the U.S.A., and in this country, were for the first time definitely recognised, though much earlier outbreaks are known to have occurred. The serious epidemics of polio-encephalomyelitis in Scandinavia in 1905, and in the U.S.A. in 1909, and the increased prevalence of this disease in Great Britain since 1910, brought into great prominence the problem of infective disease of the central nervous system due to an invisible virus. Though no visible causal microbe could be discovered, the transmission of the disease to monkeys has repeatedly been accomplished. The appearance in 1907–8 of von Economo's epidemic encephalitis added a still more intangible element to the problem. This disease is very variable clinically and is more inscrutable in its pathology, for it has proved far more difficult to transmit to animals. The experimental problem has been further complicated and the imagination stirred by the discovery of a form of acute encephalitis communicable to rabbits by means of a virus present in the vesicles of ordinary *herpes labialis*. The serious prevalence of these diseases, especially those due to filtrable viruses, has given rise to the suggestion that some new factor in modern life predisposes to, if it does not actually originate, these obscure nervous affections, and it has been argued that a widespread carrier state or constitutional susceptibility has conditioned the occurrence of an actual attack of one or other of them when some other exciting cause has lowered resistance or produced an initial lesion in the brain or spinal cord. To this confused state of pathology has entered a fresh factor—the recognition of cases of encephalomyelitis following vaccination, usually primary vaccination in adults or children after the first or second year of life. These cases, which are now well known, have been recorded in many countries and have been the subject of comment in THE LANCET.[1] The occurrence of encephalomyelitis of similar type has also been reported after measles and chicken-pox. The disease has not been certainly communicated to animals from these cases. Attention has been called by F. Redlich[2] and others to cases described as encephalomyelitis disseminata which occur independently of recognised acute infectious disease, and only last week Dr. Donald Hunter and Dr. Russell Brain referred in our correspondence columns (THE LANCET, June 16th, p. 1250) to six cases seen recently at the London Hospital which clinically came under the heading of acute disseminated encephalomyelitis, but were in no way connected with vaccination.

As Prof. J. C. G. Ledingham points out on p. 1301 of our present issue, there is no constant clinical picture in post-vaccinal nervous disturbance; at least six clinical types of nervous disease have been reported as following vaccination. Two main hypotheses have been put forward to account for the cause and nature of these cases. The first is that they are due to vaccinia virus acting alone directly on the nervous tissues; the second, which is perhaps more generally supported, is that they are due to some other latent virus, stirred into activity by the vaccinia. This activation might be attributed either to the generalisation of the vaccinia virus and the consequent onset of symptoms about the eighth to twelfth day, a time at which a general vaccinia eruption occasionally occurs, or to an anaphylactic phenomenon akin to the fever, joint-pains and rash of serum disease, following the injection of antitoxin. Two recent communications support this latter view. F. Paul[3] records four cases in adults of *encephalomyelitis disseminata* due, he believes, to the virus of poliomyelitis; from one of these two monkeys were infected experimentally. These cases, he states, exactly resembled in every way, clinical, pathological, and histological, a post-vaccinal case which he also examined. v. Mikulowski[4] related two cases, both in infants, of post-vaccinal nervous disease. One was in a child of 13 months, whose symptoms suggested encephalitis lethargica; the onset was on the eighth day after vaccination; recovery was not complete since paresis, convulsions, and athetosis persisted. In the other case, symptoms were noticed seven days after vaccination and lasted only 48 hours, but were severe and suggested encephalitis. v. Mikulowski maintains that the symptoms and pathology of cases of post-vaccinal encephalomyelitis are often identical with those of *encephalitis lethargica*. On the other hand, such experienced investigators as H. M. Turnbull, J. M. McIntosh,[5] and J. R. Perdrau[6] agree in believing the pathological histology of the post-vaccinal cases to be different from that of poliomyelitis and encephalitis lethargica, and describe a characteristic perivascular demyelination as distinctive. Perdrau, however, considers the characteristic histological features of "disseminated encephalomyelitis" to be the same whether the disease is a sequela of vaccinia or some other acute infection or occurs independently. The importance of these cases is obvious, and it is to be hoped that the request of the Ministry of Health, published in THE LANCET of April 24th, 1926, for the notification of nervous illness within four weeks of vaccination, will lead the way to early recognition and elucidation of these obscure conditions.

[1] THE LANCET, 1925, ii., 1239; 1926, ii., 509, 764; and 1927, i., 619. [2] Wien. klin. Woch., 1928, xli., 177.

PRESERVATIVES IN FOOD.

A SUPPLEMENT to the March number of the *Bulletin* of the Office International d'Hygiène Publique contains replies to a questionaire on the regulations in force in 18 countries, large and small, concerning the use of certain antiseptics in foods. Germany is the most important State unrepresented in the list. The answers suggest that there is a closer approximation in practice between different countries now than there was a few years ago. We find a fairly general prohibition of certain antiseptics and a limited use of certain other preservatives, often limited to certain specified foods; for the most part the same preservatives are allowed in the same foods. Almost everywhere there is total prohibition of formaldehyde, and its use is specifically forbidden in all foods in England and Wales, Australia, Bulgaria, Canada, the United States of America, France, New Zealand, Sweden, and Switzerland. In the reply of no country is it mentioned as being allowed. Fluoric acid and its derivatives are almost as widely banned. Boric acid and its compounds may not be used as food preservatives in England and Wales, Bulgaria, or the United States, but elsewhere their employment is permitted within specified limits—e.g., in butter, condensed milk, margarine, and cream. In Canada, for example, boric acid is permitted (1 in 400) in cream, and (1 in 200) in butter, while in France it is allowed up to 5 g. per kg. in butter and margarine. Salicylic acid and its salts are given a slightly more extended use than boric acid, although they are entirely forbidden in England and Wales, Bulgaria, the United States, and France. In many other countries they are allowed in certain foods in restricted amounts. In Canada the limit is 1 part in 5000, while there seems to be no restriction as to any particular foods; in New Zealand they are allowed in sauces, fruit juice, and non-alcoholic drinks. Benzoic acid and sulphurous acid are the preservatives most widely sanctioned.

[5] See THE LANCET, May 26th, 1928, p. 1094.
[6] THE LANCET, June 9th, 1928, p. 1201.

In England and Wales they are the sole preservatives whose use is authorised, but they may be added only to certain forms of food and only up to definite limits. The practice seems to be similar in most other countries except France, where benzoic acid and benzoates are not allowed at all. The regulations about colouring matter are even more complicated and varied and show marked differences. It is, however, generally recognised that every State must regulate the use of antiseptics and colouring matter in foods, that some of these additions are entirely undesirable and unnecessary, that certain foods do require, if they are to be kept, small quantities of preservatives, and that except for special foods like butter and cream the least objectionable antiseptics are benzoic and sulphurous acids.

BIOCHEMISTRY AND MEDICINE.

THE completion of the Courtauld Biochemical Institute at the Middlesex Hospital, which was described in our columns last week, symbolises the profound change which has come over medicine in the course of this century. As Sir Archibald Garrod pointed out when opening the Institute, the science of biochemistry was represented in medicine 50 years ago by a rack of test-tubes and a few bottles in the doctor's surgery. To-day a chain of laboratories is ready to assist the practitioner in diagnosis, treatment, and even in prognosis. His patients have the benefit of a wealth of scientific technique undreamt of by the last generation, and the family doctor fights disease not as an individual but as a member of an army with a vast organisation at his back. The science of biochemistry is comparatively new. A couple of decades ago its very name was unfamiliar, though the activities of the pathologist were already known to be expanding in chemical as well as in bacteriological directions. Now the field of biochemistry as applied to medicine is so vast that there are few diseases or disorders of function whose elucidation owes nothing to biochemical methods; moreover, some of our most effective remedies have been discovered, tested and standardised by laboratory workers. The new science plays an important part in preventive medicine, for it has evolved a multitude of tests by which the efficiency of the various bodily functions and the integrity of the various organs may be estimated, and from the results of which an accurate index of a normal man's health can be obtained. Its potentialities in this direction will be of progressive interest to actuaries. In forensic medicine the assistance of biochemistry has already proved invaluable. As to clinical medicine, the outlook in such serious diseases as cretinism and diabetes has been completely altered. With the isolation of the active principles of the ductless glands, their standardisation, and their synthetic preparation, an entirely new chapter of controlled therapeutics has been opened. On the diagnostic side the estimation of the functional activity of the stomach, kidney, and liver are of increasing importance; while changes in the chemistry of the blood and cerebrospinal fluid are being gradually but surely correlated with clinical syndromes. The colloidal chemistry of the body proteins is still in its infancy, but already light has been thrown on metabolic processes and great advances may be expected in the future.

But the hopes aroused by the development of a new science ancillary to medicine may be disappointed in two ways. The specialists who devote their life so its pursuit may lose sight of the clinical application of their knowledge, and become engrossed in theoretical studies; on the other hand, clinicians who have received less help than they anticipated from the laboratory in diagnosis and treatment may be reluctant to give adequate trial to new and complicated tests which make no claim to do more than confirm or throw doubt on clinical findings. When, however, an institute of biochemistry is situated not in academic isolation but actually in the same building as a large hospital, there must be such intimate association between laboratory and clinical workers as will ensure a constant interchange of ideas and problems. Prof. E. C. Dodds has already shown how keen and how stable is his interest in clinical problems, and workers under his direction will not fail to keep in touch with the needs of the patient. We congratulate the Middlesex Hospital on its good fortune in possessing a biochemical staff whose direct contributions to medicine are so impressive that Mr. S. A. Courtauld has already added to his munificent gift the sum of £20,000 towards the maintenance of the Institute.

OPERATIVE TREATMENT OF UTERINE CANCER.

THE chief gynæcological subject chosen for discussion at the meeting of the Nordisk Kirurgisk Forening in Gotteborg last summer was the comparative value of radiotherapy and operation in the treatment of cancer of the uterus. Dr. G. Schaanning, who dealt with the surgical aspect of the problem, has published a summary of his paper in the *Tidsskrift for Den Norske Laegeforening* for June 1st, 1928. As a former assistant of Prof. K. Brandt, he has been able to use the material of the University Gynæcological Hospital in Oslo. The period covered is from 1906 to 1925, and the number of cases of cancer of the uterus treated during this period was 562, of which 508 were cancer of the cervix, while the remaining 54 were cancer of the body of the uterus. Thanks to the comparatively stationary and controllable character of the population, Dr. Schaanning was able to trace as many as 537 of the patients. Of the 508 patients suffering from cancer of the cervix, 287 underwent some sort of operation, and 226 had a radical operation. The operative mortality of the radical operations was 10·6 per cent., but varied greatly, as might be expected, with the extent of the disease, being as low as 7·3 per cent. in early cases, and as high as 15·7 per cent. in advanced cases. What was, however, more striking and instructive was the reduction in the operative mortality during the period under review, although no fundamental change was made in the indications for operation during this period. Thus, in the five-year period, 1906–10, the operative mortality was 21·4 per cent., whereas during the period 1916–25, it was only 5·6 per cent. It is a pity that information is not forthcoming in this paper to explain such a remarkable improvement. The ultimate results were judged by the proportion of survivals without recurrence of the disease after an interval of at least five years, and it seems that only 26·7 per cent. of all the women who underwent a radical operation for cancer of the cervix could pass this test. Even when only those cases were considered in which there was no infiltration of the glands at the time of operation, the proportion of patients living without a recurrence of the disease five years or more after the operation was only 33·8 per cent. These figures give force to Dr. Schaanning's plea for an educational campaign to increase the possibilities of an early diagnosis. Such a continuous campaign is, in his opinion, the measure which is most likely to improve the prognosis. It will be interesting to note to what extent this opinion is endorsed at the forthcoming international conference on cancer.

STREPTOCOCCUS CARDIO-ARTHRITIDIS.

THE elective localisation of certain bacteria is well established; no one doubts that the bacillus of typhoid fever, however administered, is eventually localised in the small intestine. The work of Rosenow, particularly on the streptococci, certainly points to an elective localisation of these organisms. For example, 50 per cent. of the animals inoculated with a streptococcus from a cardiac valve acquired lesions in the cardiac valves; a strain from a case of chronic arthritis gave 66 per cent. lesions in the joints.[1] It

[1] Newer Knowledge of Bacteriology and Immunology. Jordan and Falk, 1928, p. 576.

is only a step from this to the theory of specificity among the streptococci, and in rheumatism we are familiar with the organisms of Beattie, Poynton and Payne, and Birkhaug. All observers agree, however, that most cases of rheumatism do not yield organisms either from the blood or in local lesions, and none of these has yet been recognised as the specific cause. The latest claimant is the "Streptococcus cardio-arthritidis" of J. C. Small, which has lately attracted some attention. Its claims, as now set out,[2] are difficult to appraise. Only three of Small's strains come from the blood; most of them are from the throat, where streptococci abound; and no evidence of any normal controls is given. Though the organism is said to be non-hæmolytic, to vary in its sugar reactions, and to be specific in its agglutinations, no cultural characteristics are adduced which would make it possible to recognise the strains. Many of the references are "in the press," others are "personal communications," and on the whole, technical details are inadequately presented. It may be noted that tests of cutaneous sensitiveness are on the whole negative, which is remarkable, since other workers have recently claimed specific results with their strains and, in fact, a surprisingly large number of rheumatic patients are Dick-positive. The author's parsimony in bacteriological information, however, is balanced by his generosity in clinical detail. Patients are treated by vaccines, by "soluble antigen," made by washing the streptococcus, and by antisera, and especially by concentrated globulin precipitates. Striking results are claimed; very exact and ample clinical details are quoted. Opsonic indices and agglutination titres show a speedy upward change; chorea disappears; valvular lesions are ameliorated. In considering these reports it should be remembered that a relatively new claim to the identification of the causal organism of rheumatic fever lends itself to criticism. Many independent investigators have incriminated the streptococcus, whereas few have produced evidence to show that other organisms might be to blame; but even if its guilt be proved the question would remain, whether one strain of streptococcus is specific for the disease or whether a variety of strains may cause it. The trend of opinion all over the world appears to favour a fresh trial of streptococcal antisera for many diseases whose ætiology is not as yet completely understood.

INDUSTRIAL ACTIVITY AND FATIGUE.

THE history of human endeavour in the past, whether in the construction of pyramids, cathedrals, industrial works, or engineering plants, has too often been a tale of effort forcefully directed by task-masters with but little care for the well-being of the labourer so long as the task progressed. Not until the beginning of this century did it begin to dawn upon employers, as a class, that maximum production is contingent on the fitness of the worker. In the eighth annual report[3] of the Industrial Fatigue Board an account is given of the way in which the work of the Board started and has since progressed, and of the gradual expansion of its activities. The problems recently submitted to the Board for solution cover a wide field and are of considerable importance. They include hours of work in relation to the value of rest pauses during long spells, and to the double-shift system for women; the physiology of ventilation with special regard to heating by the panel system; vision and lighting; accident causation; vocational guidance, and other matters. Government departments and industrial associations have sought information as to mining conditions, telegraphists' cramp, weight-carrying, and sickness in the cotton industry and printing trade. A further line of activity has been concerned with research into the principles governing muscular activity, muscular effort, and the effects of noise and vibration. Laboratory research often helps to disentangle the host of interfering factors which confuse the issue in industrial practice. Evidence, at first inconclusive, has been reinforced from different sources—for example, the increase in rate of output on short shifts, the beneficial influence of short rest pauses, the importance of high illumination in fine processes, the deleterious effects of high temperatures on work involving muscular effort, are among the conclusions which were tentatively made at first and as the result of many investigations, gradually came to be accepted. The Board is steadily gathering and propagating new knowledge, and even more important, is showing that improved conditions of work are beneficial alike to employers and workers.

STEEL DENTURES.

DURING the late war the shortage of rubber and precious metals in Germany affected, among others, the dental profession, since the construction of dentures involves either a vulcanised rubber or a gold base. As a substitute for these materials the firm of Krupp began to experiment with stainless steel as a denture base. The method soon passed beyond the experimental stage, and before the end of the war dentures of stainless steel were being made on a considerable scale. Even now that both rubber and gold are freely procurable, steel is still being used in Germany to some extent, apparently with satisfactory results. In England experiments have been chiefly directed towards finding a synthetic resin which could be coloured to resemble gum more closely than is possible with vulcanite, and these attempts have been so far successful that it is hoped that vulcanite may soon become obsolete. The German investigations have, however, stimulated some preliminary trials of steel in this country, and Mr. A. C. Hutchinson, in the *British Dental Journal* for May 15th, records some experiments carried out in the Manchester Dental Hospital with the coöperation of Messrs. Firth and Sons, of Sheffield. It appears that Krupp's use for dentures a rust-proof steel belonging to what is termed the VA group, which has a high resistance to corrosion even when soft. It contains 20 per cent. of chromium and a medium content of nickel. A denture made of this material is only half the weight of a gold plate of the same thickness, and in order to ensure equal strength the gold denture would have to be twice as thick, and would weigh four times as much. Mr. Hutchinson experimented with Firth's Staybrite silver steel and found it possible to hammer and swage the material into dental plates. Soldering, on the other hand, presented great difficulties and, so far, the search for a suitable flux has not been wholly successful; but it was found possible to attach teeth to a steel plate by means of vulcanite, and the attachment appeared perfect. The work is still in the experimental stage in this country, and the production of dentures which are satisfactory in the mouth is still some way off, though there seems to be no reason why the German results should not be repeated here. We understand that in Germany the process is complex, involving a technique not possible in a dental workshop, and that the actual swaging of the steel is carried out by Krupp's to models supplied by dentists. Nevertheless the method has distinct possibilities and we hope that Mr. Hutchinson will continue so promising an experiment.

SPASM OF THE PYLORUS IN INFANTS.

ONE effect of the introduction of Rammstedt's operation for hypertrophic stenosis of the pylorus in infants has been that a distinction is drawn between cases in which there is a palpable pyloric tumour and those in which there is not. With an experienced and careful observer it is safe to say that if a tumour cannot be felt after several examinations, and visible gastric peristalsis is well marked, the case is probably one of pyloric spasm, for which operation is contra-

indicated. The distinction between the two types of cases has led to a closer study of the ætiology of these conditions, and Dr. M. I. Rubin [1] now calls attention to the presence of an enlarged thymus in cases of pylorospasm. He has observed that in suspected pyloric stenosis the vomiting often stops after an examination with X rays. He has also found that in these cases there is commonly a history of attacks of breath-holding and cyanosis which point to the possibility of thymic enlargement. Radiograms were taken with this in view and in 13 unselected consecutive cases an enlarged thymus was seen, whereas the gland was enlarged in only one of seven cases of true pyloric stenosis. More than half of the cases of pylorospasm had symptoms suggestive of thymic enlargement, and the five which were treated only by exposure of the thymic region to X rays all showed improvement. Other observers have called attention to the possible association of enlargement of the thymus with pyloric spasm, and treatment by means of X rays or radium has also been previously reported. At the same time, as Dr. Rubin points out, it is still doubtful whether the respiratory embarrassment in these cases is really referable to an enlarged thymus, and the value of radiological examinations, more especially when negative, is not fully established. In one series of 60 infants with varying complaints X rays showed enlargement of the thymus in 29, which suggests that deductions about the connexion between thymic enlargement and pylorospasm are of uncertain value if based solely on radiological examination. A larger series of infants with pylorospasm will have to be examined and treated by X rays before such a connexion is placed beyond doubt.

THE WORK OF A POOR-LAW HOSPITAL.

Dr. A. Lionel Baly, the medical officer of the Lambeth Poor-Law Hospital, has combined with his report for last year a retrospect of the work of the institution during his 20 years' service. It is an outspoken and challenging document which not only records the progress of the last two decades but indicts boards of guardians generally for having "completely failed to appreciate their responsibilities" under the existing law, with the result that "the poor-law hospital has not been provided with adequate facilities for the treatment of patients." Had they risen to their responsibilities Dr. Baly believes that there would have been no waiting lists at the voluntary hospitals, since destitute patients would have been taken off those lists, and that consequently the question of poor-law reform would not have arisen. Even now he is satisfied that the adoption of enlarged facilities would be infinitely less costly than any of the suggested reforms. But, apart from the slow growth of the ideal that a "workhouse infirmary" should afford its patients the best that science can give, boards of guardians generally would probably reply that they have been compelled to keep the fear of the ratepayers before their eyes. In any case the opportunity—if, in the comparatively recent state of public opinion, it was an opportunity—has been lost, and poor-law reform in a more or less drastic shape is now bound to come.

That the poor-law hospitals have grown enormously in importance and efficiency of late years is well known, and the figures which Dr. Baly gives of his own experience are convincing, since it is certain that many similar institutions could, mutatis mutandis, show parallel results. Between 1912 and 1927 the number of patients dealt with at the Lambeth Hospital has increased by 80 per cent., the accidents and injuries treated by 390 per cent., and the number of operations by 592 per cent. Serious cases, as of fracture and concussion, have risen enormously, yet it is significant of the efficiency of modern methods of surgery that the deaths have increased by only 37 per cent. With the exception of the dental department practically all the new departments have been added since 1912. All this leads Dr. Baly to point out not only that the work of a first-rate poor-law institution is now that of a large general hospital, but that the poor-law institutions are the only "general" hospitals into which all classes of cases, with the exception of a few specified fevers, have to be admitted. This being so, it is obvious that for the proper classification and separation of the more serious cases from the general wards a poor-law hospital ought to be as well equipped as a voluntary one, if not better. The present mixtures of serious or dying cases with convalescent patients will, all will allow, be looked upon in the future as incredible. Dr. Baly calculates that the amount of scientific work now being done by the London poor-law hospitals is approaching that of the voluntary institutions, and that they will in time be forced to undertake a far greater proportion of it unless the hospitals outside the poor-law are enabled to increase their resources enormously.

On the difficult matter of the certification of mental cases Dr. Baly has some interesting things to say. Since he has at his disposal no suitable accommodation for mental cases he has to certify all of them, notwithstanding the almost daily pleas of the relatives of these unfortunate patients that they should be allowed to remain where they are instead of being removed elsewhere as "insane." He is fully convinced that with proper accommodation he could keep at least 25 per cent. of these patients in general wards without certification. It is fully open to boards of guardians to provide this accommodation, though it means that in London the cost would be transferred from the County Council to the union. An alteration of the law would, however, be necessary for the retention, which Dr. Baly strongly advocates, of recoverable certified cases within the walls of poor-law hospitals. This is a direction in which elasticity is needed alike for scientific reasons and as a concession to the entirely comprehensive human repugnance to the indiscriminate use of the word "insane."

THE BUNDABERG DISASTER.

IT will be recalled that a Commission was appointed to inquire into the deaths which in January followed the injection of diphtheria prophylactic into a number of children at Bundaberg, in Queensland, Australia.[1] The Canberra correspondent of the *Times* last week telegraphed particulars of the Commission's report, now tabled by Sir Neville Howse, the Federal Minister of Health. The evidence given before the Commission subsequent to our comment on Feb. 4th suggested bacteriological contamination as the cause of the accident. The prophylactic toxin-antitoxin mixture used contained an amount of nutrient broth which would, in the absence of an antiseptic, act as a good medium for the growth of any organisms fortuitously introduced. The doctor who made the injections testified that the prophylactic was observed to be cloudy on inspection the day after the injections, when the first children died. Curiously enough, the prophylactic contained no antiseptic, a point which the Commission adversely criticises, remarking that such products, unless containing sufficient antiseptic, should not be issued in rubber-capped containers for repeated use. So far as we are aware, all prophylactics and vaccines issued in rubber-capped bottles in England, America, and Germany contain from 0·3 per cent. to 0·5 per cent. of phenol, tricresol, or lysol, an amount sufficient to inhibit the growth of practically all pathogenic organisms. Though rubber-capped bottles have been much used as containers, most heads of laboratories issuing sera and vaccines dislike them. When fluid is withdrawn through a syringe needle which has been plunged through the cap, a partial pressure is produced inside and at the first opportunity air with any contamination on the cap is sucked in. Though it is possible for a trained bacteriologist repeatedly to pierce the cap of a rubber-capped bottle containing only sterile nutrient broth, without causing contamination, the risk in practice is

[1] Jour. Amer. Med. Assoc., May 26th, p. 1694.

[1] See THE LANCET, Feb. 4th, p. 249.

a real one, and there is evidence that bottles in the past have been contaminated in this way even when containing a reasonable amount of antiseptic. For sterilising the cap before puncture pure lysol or tincture of iodine is usually employed. The Commission concludes that staphylococci had been introduced by the needle through the rubber cap when the bottle was in use some days before the fatal day late in January, and that these organisms caused the deaths. These conclusions are said to rest partly on negative evidence. From the evidence given before the Commission and reported in the Australian press we know that the first symptoms of illness in the children who had been injected were vomiting, diarrhœa, and fever, coming on within eight hours. There is no mention of any organism of the food poisoning group. The symptoms described are not those usually caused by streptococci or other dangerous microbes which might suggest themselves, nor are they the commonly accepted symptoms of illness caused by staphylococci, though we must admit that we do not know much of what would happen after the injection subcutaneously or intramuscularly of the enormous numbers of cocci that might be contained in a fluid recognisable as "cloudy." The Commission apparently recommended consideration of the use of detoxicated toxin—i.e., toxoid or "anatoxine." (The cable, presumably in error, reads "antitoxin.") We have previously noted [1] that the prophylactic mixture mostly used in England contains toxoid and no untreated toxin. Toxoid alone is being used tentatively in England and by Park and others in U.S.A., and is widely employed in French-speaking parts of Europe.

The whole incident reaffirms that the price of safety in these matters is eternal vigilance, but it does not indicate any loophole in the regulations or prevalent practice in English-speaking countries, with which we are most concerned.

CONGENITAL ANEURYSM OF THE CEREBRAL ARTERIES.

SPONTANEOUS subarachnoid hæmorrhage of non-traumatic origin, of which Dr. Bruce Maclean reports a case in our present issue, has proved of great interest both to clinician and pathologist since 1859, when Sir Samuel Wilks published a paper entitled Sanguineous Meningeal Effusion (Apoplexy): Spontaneous and from Injury. As the result of his work rupture of saccular aneurysms upon branches of the circle of Willis slowly came to be recognised. H. Eppinger, in 1887, was the first to postulate a congenital basis for these aneurysms, and he demonstrated localised defects in the elastic and muscular elements of the vessel wall. He pointed out that they almost always occur at the bifurcation or branching-point of vessels and generally in the fork between the parent trunk and the origin of a branch. In this country H. M. Turnbull (1914) and E. G. Fearnsides (1916) have fully confirmed what Eppinger said. Turnbull describes the lesion as "an inherent weakness due to a congenital abnormality in the structure of the arteries at their points of junction." They established the observation, since confirmed by others, that such aneurysms may be met with at all ages from early infancy upwards and may in fact rupture at any age.

Recently the co-existence of co-arctation of the aorta and ruptured cerebral aneurysm has been recorded by several independent observers—H. L. Parker (1926), F. Parkes Weber (1927), H. W. Woltman and W. D. Shelden (1927), and F. H. K. Green.[1] This last author points out that these observations support the hypothesis of Eppinger, for "where one congenital abnormality exists it is by no means uncommon to find others." He adds that "against this may be objected the fact that in patients with aortic co-arctation it is common to find an abnormally high blood pressure in the vessels to the head, neck, and upper extremities, and this in itself might be adduced to account for the formation of aneurysms in the brain."

It is important to remember that a large proportion of all cerebral aneurysms produce no symptoms during life. A considerable number press upon or rupture into the brain, giving rise to symptoms and signs which are indistinguishable from cerebral tumour or from cerebral hæmorrhage. There is, however, one clinical picture which we owe principally to C. P. Symonds (1923), in which the aneurysm ruptures minutely and leaks slowly into the subarachnoid space. The leakage may be so gradual as to cause little or no cerebral compression, so that consciousness may not be lost. Signs of acute meningeal irritation appear—headache, pain or stiffness in the neck and limbs, a positive Kernig sign, and a dazed, irritable mental condition. The occurrence of "hæmatolytic" fever in the first ten days may give rise to suspicion of an infective meningitis, but lumbar puncture reveals a cerebro-spinal fluid which is highly characteristic (Froin, 1904). There is: (1) An even admixture of blood which is the same in a series of specimens collected at the same puncture; (2) absence of coagulum; and (3) pink, brown, or yellow colouration of the clear supernatant fluid, which is apparent when the red cells have been allowed to sink to the bottom of the tube.

The occasional occurrence of subretinal and vitreous hæmorrhages is another phenomenon of great importance. The earliest case recorded is that of Sir William Hale-White (1895). C. P. Symonds (1923), L. Paton (1924) and G. Riddoch, C. B. Goulden, and H. M. Turnbull (1924) have since discussed their ætiology and significance. The hæmorrhages result from venous obstruction due to distension with blood of the subarachnoid sheath of the optic nerve. As might be expected, they are particularly found in those cases where the ruptured aneurysm is of the anterior cerebral, anterior communicating, or internal carotid arteries. The question whether the subarachnoid hæmorrhage itself ever penetrates the lamina cribrosa still gives rise to dispute.

[1] Green, F. H. K.: Quart. Jour. Med., 1927–28, xxi., 419.

SUBSCRIBERS to the Dawson Williams Memorial are invited to attend a meeting to be held at the House of the Royal Society of Medicine, 1, Wimpole-street, W., on Tuesday, July 10th, at 5.30 P.M., to receive the treasurer's report and decide on the form of the memorial. The organising committee suggests that it should be a prize, to be awarded every two or more years, for the best work which has been done in pædiatrics since the previous award. The list of subscribers will remain open until July 10th, and contributors are invited to send their cheques to the hon. treasurer, Sir StClair Thomson, at 64, Wimpole-street, W. 1, before that date, as the list must be then finally closed.

THE eighteenth annual meeting of the Oxford Ophthalmological Congress will be held from Thursday, July 5th, to Saturday, the 7th, under the mastership of Mr. Philip Adams. The Doyne Memorial Lecture will this year be delivered by Dr. Arthur Thomson, the Dr. Lees professor of human anatomy in the University of Oxford, whose subject will be Observations on the Eyes of Birds. The full programme of the congress may be had from the hon. treasurer, Mr. Bernard Cridland, Salisbury House, Wolverhampton. An exhibition of ophthalmological instruments and apparatus will be on view during the meeting.

WE regret to record the death on June 16th of Lord Hambleden, chairman of King's College Hospital, to whose generosity this hospital owes not only its present site but many other benefactions. Lord Hambleden was a firm friend to the voluntary hospitals and a powerful worker in their interests. The institution of the Hospital Saving Association, over which he presided, and recently the development of the principle of admitting paying patients to private wards, owe much to his initiative, and his wise counsel will be greatly missed by those concerned with the welfare of the sick.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CLXXXI.—THE TREATMENT OF TIC
(HABIT SPASM).

A TIC may be defined as "a coördinated purposive act, provoked in the first instance by some external cause or by an idea" and perpetuated as a repetitive involuntary movement. The same term has recently also been applied to certain coördinated involuntary movements which are found in persons suffering from organic diseases of the nervous system—for example, epidemic encephalitis. In spite of superficial similarities these two forms of involuntary movement are ætiologically as distinct as the hemiplegia produced by hysteria and that resulting from cerebral hæmorrhage, and the word tic is employed in this article in its older and established usage of a derangement of neural function occurring in the absence of organic nervous disease. Involuntary movements of organic origin which may be confused with tic include some of the very varied disorders of motility which may follow epidemic encephalitis, especially the so-called postencephalitic "tics," myoclonic movements, conjugate ocular spasms, and the slow rhythmical movements known as bradykinesias. Other conditions which must be considered in making the diagnosis include muscular spasm due to focal epilepsy, and extrapyramidal syndromes such as chorea, athetosis, and torsion spasm.

Ætiology.

Experience has shown the following working hypothesis to be of practical value in treatment:—

There is much to be said for regarding a tic as a conditioned reflex—that is, as a motor response which through a process of association has come to be linked with an inappropriate stimulus. At first the movement which later becomes a tic is purposive, being still the response to an appropriate stimulus. For example, a child blinks because it has conjunctivitis or twists its head because its collar is tight. Why does the movement continue after the stimulus has ceased to exist? The explanation is that the movement has now become the motor response to a new stimulus which has become capable of evoking it through association with the original one and which continues to be operative though the latter has come to an end. This association is a mental process which relates the movement to new elements in the patient's environment. For example, a child's innocent and physiologically justifiable sniff or wriggle may evoke admonitions or punishment from its father or the irritated protest of its mother that "it gets on her nerves." The movement may thus become associated in the child with mixed feelings of fear, resentment, and a sense of its power to exasperate, all of which are directed towards the parent. The parent's reproof and the child's emotional reaction to it become linked with the original stimulus and acquire the power to elicit the same response. Thus the parental eye becomes a conditioned stimulus which now by itself is capable of evoking the movement. Later the movement may be called forth by any circumstances which produce in the child the corresponding state of mind, especially by anyone who stands to the child in a relationship somewhat similar to that of the parent—for example, the school-teacher. Suggestion also plays an important rôle in strengthening and establishing the pathological reaction, often operating in the well-meaning comments of relations or neighbours that "the poor child can't help it." Once established, the tic tends to strengthen in the patient, who is powerless to control it, those very feelings of inadequacy or self-pity which are usually associated with its provocation, and so to set up a vicious circle.

One more ætiological factor remains to be mentioned. The tic as a link in a causal chain is related not only to the past but to the future, and has reactions which reverberate indefinitely between the patient and his environment. He is apt to exploit his disorder as a defence against the very circumstances which elicited it, using it perhaps as a scourge to a repressive parent, a claim upon the pity of friends or a refuge from social obligations.

Psychotherapy.

The foregoing considerations lead us to the conclusion that no treatment of tic is likely to be successful which is not primarily psychotherapeutic. A lengthy analytic investigation designed to expose the patient's faulty emotional adjustments and to re-educate him is at present limited to the few, but fortunately much can be done without prolonged investigation, especially in early cases, by those conversant with the principles involved. Such short cuts may be theoretically unjustifiable but they have the double pragmatic sanction of necessity and success. The practitioner should recognise that the movements are a symptom of a faulty mental adjustment, and should endeavour to find an answer to the following three questions: (1) What is the stimulus—i.e., the factor in the patient's environment, which evokes the movement? (2) What is the emotional state with which it is associated? (3) What psychological end does the disability serve? Inquiry along these lines, if conducted with sympathy and tact, may lay bare feelings of inadequacy, embarrassment or shame which go the root of the symptom and indicate the lines along which the readjustment of the individual must take place.

Conscious Re-education.

Conscious re-education consists of the practice by the patient of exercises involving: (1) muscular relaxation and immobility, and (2) orderly movement of the affected parts of the musculature. The physiological basis of this mode of treatment probably consists in the fact that both voluntary relaxation and orderly movement of affected muscles involve at the level of the cerebral cortex inhibition of the pathological conditioned reflex which constitutes the tic.

1. For the practice of muscular relaxation the patient should be placed in the position in which the tic is least troublesome, which will usually be lying down. He is first instructed to practise a general relaxation of all his muscles, and later his attention is directed to the affected part of the body and he practises immobility of the affected muscles for periods of gradually increasing length.

2. He next practises exercises which involve orderly movement of the affected part, and which can easily be devised to meet the requirements of each case. Thus a patient suffering from a blinking tic is made to open and close the eyes slowly to order. Tics involving the lower part of the face are treated by opening and closing the mouth, protruding and withdrawing the tongue, retracting and pursing the lips, &c. Spasmodic torticollis requires movements of rotation and flexion of the neck. These re-educative exercises are first carried out under the supervision of the physician and the patient is then instructed to practise them alone several times a day in front of a mirror. A child naturally requires adult supervision for this purpose. Reading aloud is a useful exercise for patients with any form of facial tic, also Swedish remedial exercises. No exercises should be carried to the point of fatigue.

Hypnotic Suggestion and Re-education.

The usefulness of suggestion in treatment is limited by the fact that it does little to correct the patient's mental maladjustment. When used alone, therefore, suggestion is unlikely to produce a permanent cure, at least in adults, though it may afford striking temporary relief. The most effective way of employing it is in the hypnotic state. The patient is hypnotised and often, until the process becomes familiar to him, he exhibits an intensification of his involuntary movements during the early stages. The first suggestion given is of complete muscular relaxation and cessation of the movements. As soon as this is achieved the patient's attention is directed to the fact that he has succeeded in controlling the tic. At the first two or three treatments it is wise to be content with reaching this point and concluding with general suggestions of recovery. The next step is to begin hypnotic re-education, which consists in causing the hypnotised patient to carry out the re-educative exercises which have been described in the previous section, at the same time emphasising to him his capacity to do this successfully. By means of hypnotic suggestion the process of re-education may be shortened and the rapid improve-

ment of which the patient is conscious during his waking life is of considerable psychological value.

Direct suggestions of improvement made to the fully conscious patient are of less therapeutic value except perhaps in children, but indirectly suggestion assists the curative powers of other measures.

Surgical Treatment.

Apart from theoretical objections to the surgical treatment of tic there are few tics in the treatment of which surgical measures are practicable, and spasmodic torticollis is now almost the only one which brings the patient into the surgeon's hands. Surgery can at best be only palliative and cannot hope to achieve a radical cure; moreover, since tic is a disorder of movement and not of individual muscles, it is insufficient to put out of action only the muscles which have hitherto been involved. As J. M. T. Finney and W. Hughson say, "not infrequently, when one muscle or group of muscles—those primarily involved—are put out of commission by the operation, the affection immediately manifests itself in an adjacent set of muscles or may even involve the opposite side." However, if the operation carried out is sufficiently extensive to immobilise the affected part the suggestion of cure may be so strong that the movements do not recur when function returns.

Many surgical measures have been employed in spasmodic torticollis since Minnius, in 1641, first treated the condition by open section of the sterno-mastoid. The greatest prospect of success would appear to be offered by the operation practised by Finney and Hughson which involves bilateral resection of the spinal accessory, suboccipital, great occipital, and third cervical nerves, and which they claim yielded complete cure in 12 and improvement in a further 16 out of 32 patients operated upon. Operations for the relief of facial tic cannot be recommended.

Other Therapeutic Measures.

All available means should be employed to maintain the general health at a high level, since tics are always more troublesome when the patient is fatigued or "run down." Sedative drugs are useful adjuvants to other modes of treatment. The bromides are of help both in children and adults, and possess the physiological justification that Pavlov has shown that they strengthen the inhibitory processes of the cerebral cortex. Adequate sleep must be ensured to the patient, if necessary by the exhibition of soporific drugs. Bromides are usually sufficient for this purpose in childhood, but adults may require medinal grs. 7½, or luminal gr. 1 at bedtime. Nothing is to be expected of massage, electricity, or orthopædic appliances. In the rare cases in which the original stimulus to the movement is still present when the patient comes under observation, it will require appropriate treatment. Conjunctivitis, refractive errors, dental caries, enlarged tonsils and adenoids may thus need to be dealt with.

Special Points in Children.—The whole household must unite in a conspiracy to take no notice of the child's movements, except as may be necessary to carry out the prescribed treatment, and all forms of punishment and reproof must be prohibited. If no improvement results the child should be sent to relatives in another town for a time, or admitted to a suitable hospital. In some children an attack of chorea appears to form the starting-point for tics; this sequel is to be avoided by thorough treatment and prolonged convalescence after the attack. Imitative tics are especially prone to occur in children, and the presence of a near relative suffering from a similar disorder is a strong reason for treating the child away from home. Lastly, it is impossible to over-stress the importance of early treatment since tic in childhood is eminently curable, while in adults it is apt to be one of the most intractable of functional nervous disorders.

MEDICINE AND THE LAW.

Dangerous Drugs Act Prosecution Fails.

ON June 4th, after taking time to consider his judgment, Mr. Gill, the Westminster magistrate, dismissed a summons against Mr. Robert Lee Dillon, who was charged with obtaining morphine with prescriptions supplied simultaneously from two doctors without disclosure to either doctor that he was being treated by the other. It is a pity that the law on matters of this kind should be contained in departmental regulations and not in the direct legislation of Parliament itself; and, indeed, the position is not so clear but that it may be well to remind practitioners of how the matter stands. In 1921, Regulation 7 of the Regulations of May 20th declared that "no person shall be in possession of any of the drugs" (i.e., morphine, cocaine, &c.) "unless . . . he proves that the drug was supplied for his use by a duly qualified medical practitioner or registered veterinary surgeon or on and in accordance with such a prescription as aforesaid." In October, 1922, a fresh set of Regulations added the words "or attempt to obtain possession of," after the words "No person shall be in possession of." Finally, in 1926, after the report of the Departmental Committee on Morphine and Heroin Addiction had been published and considered, a further paragraph was added at the end of Regulation 7, as follows:—

"Provided that the last foregoing provision shall not apply to any drug supplied to a person for his use by a medical practitioner or in accordance with a prescription if that person was at the time of the supply in course of receiving treatment from another medical practitioner in respect of addition to any of the drugs or otherwise, and of being supplied with any of the drugs by or on a prescription given by that last-mentioned practitioner, and did not disclose that fact to the first-mentioned practitioner before the drug was supplied to him."

In framing the law on these lines the Home Office rejected a suggestion to make it obligatory upon doctors to notify to the Home Office any case in which a person is being treated by the continuous administration of morphine or heroin. It was realised that notification would help the Home Office to detect cases where patients were obtaining supplies concurrently from two or more doctors; but the opinion of the Committee was accepted that notification would impair the confidential relations of doctor and patient and that the benefits of the proposal would hardly outweigh the disadvantages. In the recent case before Mr. Gill the defendant had been treated for repeated attacks of malaria. The magistrate decided in his favour, since there had been no continuity of treatment by two doctors concurrently at the material time.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Social Standing of Medical Students.

THE Leipziger Verband has just published figures dealing with the social standing of medical students in the Prussian Universities. The total number is 4282, including 671 women, and in the report they are divided into three categories, according to whether they come from the upper, middle, or lower classes. Children of the higher Government officials, professors, teachers with academical degrees, clergymen, lawyers, medical men, authors, officers in the army, big landowners, proprietors or managers of large factories and banks, and private employees in high positions, are placed in the first category. The second includes the children of Government officials in secondary positions, small farmers, soldiers, trades-

people, and private employees. In the third category they place the children of workmen, labourers, and minor officials. Of the men students 40·4 per cent., and of the women 52 per cent., fall into the first category, whilst in the second are 57·3 per cent. of the men and 46·7 per cent. of the women, and in the third 1·5 per cent. of the men and 0·5 of the women. (The social standing of 0·8 per cent. of the students could not be ascertained.) Thus the majority of the women students come from the upper classes, but amongst the men the middle classes predominate.

Sale of Medical Practices.

Formerly the sale of medical practices was forbidden not only by the courts of honour as being against the ethics of the profession, but also by the law courts, which often declared contracts of the sort invalid. Recently, however, these views have undergone a certain change. A Berlin lawyer, writing in the *Medizinische Welt*, says that the High Court has recently, on two occasions, declared that the sale of the practice of a deceased medical man by his heirs is valid. Sometimes it is agreed, and has been considered lawful, for the money not to be paid in one sum, but in instalments, and in some cases the vendor continues to receive a share of the income derived from the practice by his successor. The contract must not contain any provision which may tend to deceive the public. For instance, if a provision is made in the contract whereby it is agreed that the vendor's door-plate may continue to be used for a time in order to make the public believe that he is carrying on his practice, such a provision would be contra bonos mores and thus invalid. A case is on record in which a medical man purchased a practice under the condition that he would pay an excessive sum for it, and the High Court objected to the contract on the ground that it would result in the purchaser being induced to extract as much money as he could from his patients, which would be morally unjustifiable. A contract in which it was agreed that the purchaser of a practice should prescribe remedies and preparations devised by the predecessor was also declared invalid. In the eyes of the High Court the medical profession is not a trade in the usual sense of the term, but a public service. Economic questions, therefore, must take a secondary place in the government of its affairs.

The Berlin Municipal Hospitals.

The state of the Berlin municipal hospitals was lately discussed before the Berlin Society for Public Health. Dr. Korach said that the number of beds was obviously too small, so much so that during the recent spread of diphtheria it had been suggested that schools and other public buildings should be converted into hospitals. The municipal hospitals, especially the new ones, are nearly all situated in the suburbs, far from the centre of traffic, and this, according to him, is a drawback for persons injured in street accidents, who have to go a long way before they can be treated; hospitals which would deal with accidents only ought to be established in the centre of the city. Another drawback of the municipal hospitals is that, with the exception of the Virchow Hospital, they have only internal medical and surgical departments, none being provided for nervous diseases, orthopædics, or urology. There are special wards for children's diseases of which the official head is the head of the internal department; in practice, however, the head of the department is an assistant who is interested in that particular branch of medicine. Dr. Korach pleaded for the establishment of special departments, particularly for occupational diseases. Prof. Hofmann, of the municipal health office, stated that to overcome the shortage of beds a new hospital would be erected this year, that the old hospitals had been enlarged and modernised, and that a large private hospital had been taken over by the city. In the new hospitals special departments will be set up, but this was not practicable in the existing ones.

Avertin in Confinements.

At a meeting of the Berlin Gynæcological Society Dr. Hornig has reported on the results obtained with avertin in confinements. In only 75 per cent. of 180 cases has he found it effective as an anæsthetic. The drawbacks to its use were that labour pains became weaker and the second stage was prolonged. Separation of placenta was sometimes made difficult, and atonic hæmorrhage developed. Moreover, in some instances, a state of excitement was observed which was detrimental to an aseptic course of the delivery. He is therefore unable to recommend avertin for obstetrical purposes.

The Minister for Public Instruction, in agreement with the State Examination Commission, has laid it down that candidates who have twice failed to pass a part of the State examination may not take it again. He considers that candidates who have twice proved themselves unable to pass the examination, though they have had time enough in which to prepare, must be regarded as unfit to become qualified medical men.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Essentials of a Spa.

AT the recent congress of the Hungarian Balneological Society, Prof. Alexander Korányi said that the progress of science has caused a great change in the requirements which a health resort should satisfy. The modern spa must be a serious institution for treatment on a proper scientific basis. This can only be achieved under the following conditions. First, it must not be a place of entertainment; for as such it cannot be developed and face competition. It must be specialised, and accordingly must receive only patients who are likely to benefit by its particular advantages. It must be served by competent up-to-date specialist doctors, whose presence makes it possible to carry out scientific work connected with the diseases which the methods in use—e.g., baths—are expected to cure or alleviate. There must be hospitals, laboratories, and equipment to ensure that patients shall receive adequate treatment. The organisation of the place must be adapted to the requirements of the patients, and the final control must be in the hands of medical directors of the baths, without regard to the views held in non-medical quarters. An examination of foreign spas shows that the places working on these lines are the most prosperous, while those in which there is no systematic management, where the health of the patients is of secondary importance, and the interests of hotel-keepers are placed in the foreground, are incapable of meeting competition.

Problems of Psycho-analysis.

In an interview given to a medical journal, Dr. Alexander Ferenczi, president of the Hungarian Psycho-analytical Society, said that for the last year or so two important problems had been receiving the attention of most psycho-analysts—namely, analysis by laymen, and the part which should be played by psycho-analysis in education. In particular, Prof. Sigmund Freud and his adherents hold the view that the medical profession is unable to fulfil the immense task of giving the treatment required by all the neurotics, the children inclined to crime, the quarrelling families, and the workers who are inefficient owing to mental conflicts, and that therefore the services of specially trained lay analysts could not be dispensed with. On the other hand, there is a group of prominent psychologists who maintain that only a person holding a medical diploma ought to be permitted to carry out psychological research on new lines and to apply psychological methods to treatment. In Berlin, in America, and even in Paris, many prominent laymen are working in the field of psychological practice and theory. In America, great numbers of the so-called

social workers, and workers in mental hygiene, acquire competent training in the different methods of psychology. Dr. Ferenczi had the opportunity of gaining an insight into the internal life of the staff of the huge warehouse of the Macy firm, employing 10,000 persons, and was surprised to find that there are social workers, mainly well-educated women, who occupy themselves with the mental conflicts of the workers, study their intellectual tendencies, and endeavour to establish an equipoise in their family life and working condition. A group of health workers have acquired special training in nursing and looking after patients who are mentally abnormal. They have their own separate quarters, where they are consulted by those in need of their advice.

On the second question less definite conclusions have been reached, says Dr. Ferenczi, and it is a matter of keen discussion how best to utilise our psycho-analytical knowledge in the education of children and in the upbringing of the very young. One of the pioneers of the cautious combination of psycho-analysis and pedagogy is Freud's daughter, Anna Freud. Only practice and experience over many years will show what the method can effect in education.

Hungarian Rontgen Society.

The membership of this society has now risen to 167, and the scientific meetings which it organises have attracted unexpectedly large audiences. The programmes have been long and varied. Its activities are greatly assisted by the journal which it issues (the *Magyar Röntgen Közlöny*). Post-graduate courses are arranged every year. The society is arranging to produce an up-to-date treatise on the subject and hopes to arrange coöperation with foreign countries. The president is Dr. Béla Kelen, professor of rontgenology in the University of Budapest. The suggestion has been made that the authorities should be persuaded to make this subject a regular and compulsory part of the medical curriculum at the Hungarian universities.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

The Cost of Medical Care.

FOR some three years a small but influential group of physicians, economists, and sanitarians has been concerned with problems related to the increasing cost of medical care. On April 1st, 1926, following an informal conference at Washington, a committee was appointed to develop plans for a comprehensive survey of the situation. This committee has grown until it now comprises 42 persons, of whom 23 are medical graduates, and the remainder prominent economists and representatives of the public interest. The chairman is Dr. Ray Lyman Wilbur, president of Stanford University, and a past-president of the A.M.A. Dr. C.-E. A. Winslow, of Yale, is vice-chairman, and the director of studies is Dr. Harry H. Moore, whose publications on "Public Health in the United States," and "American Medicine and the People's Health," are no doubt well known in England as here. A five years' programme of inquiry has been evolved, designed to answer the three following questions:—

1. What data are now available showing the incidence of disease and disability requiring medical services, and what are the established facilities for dealing with them?

2. What do existing services cost the people and what return accrues to the physician and other agents furnishing such services?

3. What specially organised facilities for medical care serving particular groups of the population may now be found, and how do they compare in adequacy and economy with unorganised services?

Such data as have been already collected indicate that the committee is engaged on an investigation of great import. The average earnings of 30,000,000 people industrially employed were, in 1925, in the neighbourhood of $1250. Since more than one member of a family may be employed, the average family income of this class is probably around $2000. The income required to maintain a family of four in the Eastern States at the end of 1925 was estimated at $1550. That many families cannot pay their doctor's bills in time of sickness is a matter of experience as well as a valid conclusion from such figures as those above. The cost to the patient of medical service is high. For example, the *minimum* cost of maternity service by a general practitioner is, according to the Metropolitan Life Insurance Company, about $150, and a specialist's cure costs from $400 to $500. Yet the doctors do not get rich. I am reliably informed that for the small town from which I am writing the average net income of the physicians is less than $2000 a year. The expense of running an office is considerable; the amount of free work is often very high. It is said that in one large city the majority of tonsillectomies are performed free of charge. An alternative to free work and bad debts would seem to be insurance, but the profession is almost solid in its aversion to anything that resembles "State medicine." It is almost universally believed that English doctors are suffering martyrdom from this system. Is it possible that the insurance principle can be introduced without the patronage or supervision of the State? One of the studies outlined is to investigate "the extent of private medical service on a yearly basis." Others deal with such questions as organised medical service in large industries and organised health services in universities and colleges. The coöperation of the Metropolitan Life Insurance Company makes it certain that the type of health assurance which they have so successfully sponsored will also be taken into account.

HARVEIAN SOCIETY OF LONDON.

THE annual dinner of this Society was held on Thursday, June 14th, at the Connaught Rooms, London, W.C., Dr. Herbert French, the President, in the chair.

After the loyal toasts Mr. H. W. Carson, President of the Medical Society of London, proposed the prosperity of the Harveian Society, one of a triumvirate, the others being the Medical Society of London and the Hunterian Society, which escaped the great fusion whose result was the Royal Society of Medicine. Of these the Hunterian Society had been largely associated with the London Hospital, while the Harveian Society had been specially connected with St. Mary's Hospital, but the lists of membership showed that the constituent practitioners were really recruited from all schools, and in many cases men were members of two or more of the societies. The annual dinner of the Harveian Society was a function, he understood, which owed its origin to Sir D'Arcy Power and Dr. William Hill, to whom the idea occurred during their secretaryship, appositely, he thought, inasmuch as the former, as an archæologist, would see to the age of the vintages, while the latter specialised in the region of the gullet. Mr. Carson recalled to the minds of the assembly the founding of a prize in connexion with the Harveian Society by Mr. Buckston Browne in memory of his son, and then asked the company to drink the health of their Chairman, the Physician to His Majesty's Household.

Dr. French, in reply, was glad to give a thoroughly good account of the position of the Society. The number of members was going up, the financial position was sound, while the debates had been often of great interest because of the prominent part played in them by general practitioners, and this had always been a special aspect of the Society's activities. Pointing out that the toast which was to follow would receive reply from certain distinguished guests, the Chairman said that, as a matter of fact, everyone in the room was a guest, the guest of a member of the Society who desired to remain anonymous. This same open-handed member, he added, had announced

the intention not only of defraying all the expenses this evening, but of giving, now and not by testamentary disposition, a sum of money to the Society for the purposes of the annual dinner, the impulse for his generosity being the large number of friends whom he had made through membership of the Harveian Society in his early days of practice.

At this point Mrs. Kate Philips recited the humorous ballad, the "Browns of Walham Green," whose sad plight, as the result of over-attention to medical edicts laid down by THE LANCET, was followed with much amusement by the audience.

The toast of the visitors was proposed by Mr. C. W. G. Bryan, who said that in giving the health of the guests he was really putting forward over 99 per cent. of the company, whose case had been already dealt with by Mr. Carson. He briefly enumerated the principal visitors, naming the Services or Societies which they represented, and associated with the toast Mr. Augustine Birrell, Surgeon Vice-Admiral Gaskell, and Sir Henry Curtis Bennett.

Mr. Birrell, in reply, said that he had known Mr. Buckston Browne since 1861, for they had been at school together; he had dined with him frequently during that long friendship, and now it appeared he was his guest again. He had some sense of grievance he said, that the name of Harvey had never been mentioned at this dinner of the Harveian Society, because, on learning that he would have to reply for the visitors, he had read up the life of Harvey as written in the "Dictionary of National Biography" by his old friend Norman Moore. To the knowledge of the circulation of the blood thus gained he would contribute the personal observation that nothing quickened the circulation of the blood of an author more certainly than a quick circulation of his books.

Among those present at the dinner were the President of the Royal College of Physicians of London, the Master of the Apothecaries' Society, the Directors-General of the Medical Staff of the Army and of the Air Force, the Presidents of the Royal Society of Medicine, the Medico-Legal Society, the Hunterian Society, the West London Medico-Chirurgical Society, the Chelsea Clinical Society, the Regius Professor of Medicine at Oxford, the Curator of the Hunterian Museum, and the Secretary of the Royal College of Surgeons of England.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the 1927 statistics of a group of districts of varying local government status:—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Diarrhœa, &c., under 2 years.	Maternal mortality from childbirth.
West Ham C.B. (315,400)	18·9	11·0	1·10	1·11	2·7	1·5	67/26	5·7	3·0
Leicestershire C.C. (283,700)	17·2	11·6	0·97	1·35	2·2	1·5	65	2·9	3·5
Northampton C.B. (93,260)	13·7	12·0	1·29	1·42	2·1	1·7	61/37	5·5	5·5
Cambridge B... (58,680)	13·9	12·7	0·95	1·36	3·0	1·2	55/29	2·4	0·0
Stafford B. .. (28,830)	15·8	10·0	0·83	1·11	1·9	1·3	48/26	4·4	4·4
Bentley-with-Arksey U.D. (16,170)	19·2	11·1	1·05	0·74	1·5	1·4	70	0·0	6·4

West Ham.

Dr. F. Garland Collins reports that the sanatorium, with accommodation for 40 children suffering from pulmonary tuberculosis, on Langdon Hills was opened in November. The site comprises 100 acres and is in one of the highest parts of Essex overlooking the mouth of the Thames. It is about 20 miles from West Ham and 270 ft. above sea-level. The existing farmhouse has been adapted for the nursing staff and the new buildings are of the bungalow type and constructed of "Frazzi" material. This institution will obviate the necessity of sending away children to outside sanatoriums. An artificial sunlight clinic in connexion with the maternity and child welfare work was begun in 1925. During 1927, 684 patients were treated and a proposal to extend this treatment to school-children has been forwarded to the Board of Education for their approval. A dental clinic has been inaugurated for children under 5 years of age. A scheme is now before the Board of Control for the establishment at Ockenden, Essex, of a colony to accommodate 500 variously graded mentally defective persons from West Ham and other districts. The colony is so planned as to be capable of being made available for 1000 cases. Dr. Collins points out that West Ham, like the rest of the country, has felt acutely the lack of suitable institutional treatment for mental defectives.

West Ham suffered considerably from the floods which occurred in the beginning of the present year. No less than 2874 dwellings were involved, but prompt and vigorous action prevented undue hardship among the victims. Diphtheria was unusually prevalent during the year, the notifications numbering 954 and the recorded deaths 40. The council have now provided facilities for the immunisation of children.

Dr. Collins is not favourably impressed with the methods of some of the recent plants for dealing with refuse. He criticises in particular the revolving belt and the hand-sorting of all kinds of objectionable refuse. When heating or cooking is done by gas or electricity the material put in the dustbins is liable to be more noxious. Proceedings were taken against a company which dealt with the skinning of rabbits, hares, cats, and dogs, for carrying on the business of a fellmonger without a licence. The summons was dismissed with costs against the corporation, apparently as the result of expert evidence to the effect that the only animals dealt with by a fellmonger were sheep and lambs. Dr. Collins states that at one of his visits to the premises he saw an accumulation of dead cats and dogs in various stages of decomposition.

The residential open-air school for 80 boys near Ongar and the day open-air school for 60 girls did good work, and both escaped infection during an extensive epidemic of scarlet fever. Of the samples of designated milks tested 4 "Certified," 4 out of 10 "Grade A (T.T.)," 7 out of 8 "Grade A," and 31 out of 36 "pasteurised" attained their respective standards. This result was better than in the previous year.

The work done by the "home helps" employed by the council is found to be of great value in saving the mothers from getting up too soon after confinement; 1067 mothers were provided with this assistance. Of the 80 midwives who practised during 1927, only one was untrained, and she retired at the end of the year. The births numbered 5991 and 3701 were attended by midwives, who summoned medical help in 695 cases. Particulars are given of the 18 deaths from pregnancy or childbirth. Three of these were due to miscarriages in the first three months of pregnancy and in the case of one there was a definite history of an abortifacient having been taken. Of the remaining 15, 4 were sent into hospital as emergency cases and 11 were delivered at home. Three of the cases had attended the antenatal clinic, of whom one developed eclampsia suddenly, another was taken ill while away on holiday, and the third died from ante-partum hæmorrhage (probably placenta

prævia). Dr. Collins is strongly of the opinion that amongst expectant mothers the practice of taking noxious ecbolic drugs is very prevalent, and is increasing, and that the health of the mothers and the vitality of the infants is affected thereby.

Leicestershire.

Dr. J. A. Fairer divides his county by occupations into "agricultural," "industrial," and "mining and quarrying" areas. The nutrition of the school-children in the agricultural areas is the best. There was some evidence that the coal stoppage of 1926 influenced adversely the nutrition of the younger children in the colliery districts, but it was a matter of interest that the colliery districts escaped the epidemic of poliomyelitis. During 1927 there were only 9 cases of poliomyelitis notified as compared with 72 in 1926. Full investigation by Dr. J. M. Mackintosh of the present condition of the sufferers by the 1926 epidemic is included in the present report. Practically no light is thrown on the means by which the infection was spread. Of 80 cases investigated 9 died directly from poliomyelitis and 2 from bronchopneumonia during 1927. Seven recovered completely, 14 showed a mild degree of paralysis, 29 had a moderate degree of paralysis and usually wore apparatus, 11 had severe paralysis and were unable to walk without apparatus, while 8 were practically helpless and unable to walk even with apparatus. The foregoing statement applies to the condition after the lapse of one year. During 1927 the county council approved the provision of ten beds for orthopædic cases at the Manfield Orthopædic Hospital, Northampton. Four of the beds are intended for surgical tuberculosis, three for the maternity and child welfare centres, and three for the school-children. The selection of the cases is made by the honorary surgeons of the clinic at the Leicester Royal Infirmary, which institution, Dr. Fairer says, carries nearly the whole burden of hospital treatment in a county in which the voluntary spirit is strong.

Dr. Fairer makes special complaint of the tents, vans, and sheds which have come into use as dwellings owing to the house shortage and which are entirely unsuitable for the purpose. On a fine day the surroundings of these so-called dwellings are highly unsatisfactory, but on a stormy, snowy, or wet day "the state of affairs is truly appalling." It is suggested that matters might be improved by the adoption of Section 43 of the Public Health Act of 1925.

Twenty-two complaints of tuberculous milk were received from outside authorities: 22 dairy farms were visited, but only two offending cows were discovered.

Northampton.

Dr. Stephen Rowland refers to an interesting occurrence in this county borough on Dec. 7th last. A prominent citizen of the town, to mark his eightieth birthday, invited all the octogenarians to luncheon, and this brought out the fact that at least 777 residents had reached or exceeded this age. The daily consumption of milk is 5000 gallons, of which 150 are "Grade A (T.T.)," 1700 "Pasteurised," and the rest ordinary milk. Dr. Rowland refers to the fact that the milk trade is gradually coming to be regarded as one which requires special training and special premises. Towards the end of January the arrival of an influenza epidemic was heralded by the announcement that the attendance in the infants' department of one of the schools had fallen to 40 per cent. By the end of February the epidemic had passed from Northampton. The deaths attributed to it were 54, all of them at ages over 15. In the pandemic year 1918 there were 207 deaths, and a noticeable feature of the 1927 epidemic was the rapid recovery made by most of the patients. The late notification of pulmonary tuberculosis results in a longer waiting-list of patients for the "advanced" wards than for admission to Creaton Sanatorium. In 1927 the percentage of early notifications was 18, of intermediate 62, and of advanced 20, whereas in 1926 the percentage of early notifications was 36, of intermediate 48, and of advanced 16.

Cambridge.

Dr. Andrew J. Laird draws attention to the fact that 21 of the 45 infant deaths in the borough occurred during the first week of life. For the second year in succession there were no maternal deaths from childbirth in Cambridge.

A successful Health and Cleanliness Exhibition, opened by the Vice-Chancellor of the University, was held in the Guildhall, March 29th to April 2nd, and attracted about 7000 visitors. A very complete programme of lectures and films was arranged. A clean milk competition was conducted from July, 1926, to June, 1927, and attracted 13 producers and 12 retailers as competitors. Monthly samples were taken for analysis and the results were communicated at once to each competitor. The tests included total bacterial count, *B. coli* content, keeping quality, sediment, and fat content. Of the 13 producers five reached the Grade A standard for more than half the tests. The retailers did not do so well, and the conclusion was reached that milk retailed by men who also produce it is cleaner than milk bought by a retailer from someone else. "The competition," says Dr. Laird, "has proved extremely valuable."

Stafford.

Dr. J. T. Macnab mentions that housing for the poorer families of the borough promises to reach at least a partial solution if the proposal to build some lower rented houses on the new estate bears fruit. Stafford has its share of slum houses, although they are not massed together in slums. Within the last few years stables, cowsheds, and even a "duck-pen" (so called) have been seized upon by tenants, who required houses, and there are a good many occupied houses in the town to-day which are not greatly superior. If a real effort is to be made to grapple with this problem the management of the proposed low-rented houses will require special consideration, and Dr. Macnab favours the Octavia Hill system. As an example of what can be done by such a system he cites the special visitation by the health visitor of 20 houses built in 1924 for poorer families. The first section of the new sewage disposal works on the activated sludge principle dealing with one-sixth of the sewage has turned out a consistently satisfactory effluent for more than two years, and it is hoped that the remaining sections will be completed during 1928. The waste water closets which number over 2000 still continue to give trouble owing to stoppages. They are gradually being converted to ordinary water closets. In Stafford industrial smoke is small compared with domestic smoke. Dr. Macnab thinks that the present-day tendency for local authorities to urge citizens to burn their own refuse is a retrograde one. The modern destructor is especially designed to consume its own smoke, and this is not likely to be achieved in the domestic grate when the householder burns his own refuse. The domestic smoke so produced helps to soil the neighbours' washing, so that any small saving in rates is counterbalanced by extra cost of soap and cleaning materials. During the last three years over 3000 gas and electric heating appliances have been installed in Stafford.

Bentley with Arksey.

Dr. A. B. Dunne says the main industry of this urban district is coal-mining, the men being mostly employed in the Bentley Colliery, but a large number work in outside collieries and are conveyed to and fro by motor bus. The Bentley Colliery maintain two pumping stations to drain the land lowered by the colliery workings. The infant mortality-rate was 70 as compared with 98 in the previous year, and has only once before approached this figure—namely, in 1912, when it was 68. The houses in the district are brick houses of a good class usually built in pairs and about 12 to the acre, and with good-sized gardens attached. During the year the condition of the vans

and sheds in various parts of the district has created a difficult problem for the council, which has not yet been solved. The 66 notified cases of small-pox were all admitted to hospital and there were no deaths. There were 76 notifications of diphtheria as compared with 18 in the previous year. The season was an extraordinarily wet one and most of the district is below the 25 ft. contour level.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 9TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 365 (last week 286); scarlet fever, 1562; diphtheria, 898; enteric fever, 62; pneumonia, 1227; puerperal fever, 59; puerperal pyrexia, 92; cerebro-spinal fever, 7; acute poliomyelitis, 8; encephalitis lethargica, 27; typhus fever, 1; dysentery, 12; ophthalmia neonatorum, 111. No case of cholera or plague was notified during the week. The case of typhus fever was notified in Stepney Metropolitan Borough, and was reported in our issue of June 16th, p. 1224.

The cases of small-pox were notified from the following 26 counties: London, 49 (Lambeth 1, Poplar 1, St. Marylebone 20, Southwark 2, Wandsworth 24, City of Westminster 1); Bedford, 4; Berks, 1 (Maidenhead); Chester, 2; Cornwall, 1; Derby, 10; Durham, 98; Essex, 1 (Leyton); Gloucester, 1; Hereford, 1; Kent, 1 (Bromley); Lancaster, 17; Norfolk, 8; Northumberland, 20; Nottingham, 12; Soke of Peterborough, 1; Southampton, 1; Stafford, 18; Surrey, 2 (Mitcham); Warwick, 6; Yorks, East Riding, 2; North Riding, 6; West Riding, 49; Brecknock, 2; Glamorgan, 21; Monmouth, 31.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on June 12th–13th was as follows: Small-pox, 67 under treatment, 2 under observation; scarlet fever, 1782; diphtheria, 2032; enteric fever, 22; measles, 818; whooping-cough, 146; puerperal fever, 17 (plus 17 babies); encephalitis lethargica, 122; poliomyelitis, 1; "other diseases," 26. At St. Margaret's Hospital there were 19 babies (plus 15 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 34 (12) from measles, 6 (2) from scarlet fever, 32 (5) from whooping-cough, 27 (8) from diphtheria, 33 (5) from diarrhœa and enteritis under two years, and 42 (7) from influenza. The figures in parentheses are those for London itself.

Of the fatal cases of measles outside London, 7 occurred at Liverpool. Of the fatal cases of whooping-cough outside London, 3 were reported from Birmingham, 10 from Liverpool, 4 from Manchester, and 3 from Newcastle-on-Tyne, while Glasgow showed 6 deaths for the same week.

The number of stillbirths registered during the week was 281 in the great towns (corresponding to a rate of 36 per 1000 total births), including 47 in London.

DONATIONS AND BEQUESTS.—The late Mr. L. J. Friedlander, whose estate is valued at £145,818 with net personalty of £131,722, among other bequests, left £20,000 in trust for his sister and then to such hospitals as his executors may select, while half the residue of the property is similarly left to his executors for hospital charities.—Sir William Selby Church left £1000 to the Royal Society of Medicine and £100 to Epsom College.—Mr. Charles Edward Burnby, Sheffield, has bequeathed £500 each to the Sheffield Royal Hospital, the Sheffield Infirmary, the Jessop Hospital, Sheffield, and the Sheffield Blind Institution.—Mr. Laurence Maclaren, of Liverpool, made bequests of £17,000 to charities, including £5000 to the Royal Southern Hospital, Liverpool; £2000 each to the Liverpool Royal Infirmary and the David Lewis Northern Hospital; £1000 each to the Bootle Borough Hospital and the Royal Liverpool Children's Hospital; £500 each to the Stanley Hospital, Liverpool, and the Liverpool Home for Incurables; £300 to the Woolton Convalescent Institution; £1000 to the General Public Hospital, St. John, New Brunswick, Canada; and £250 each to the Home for Incurables and the Association for the Prevention of Tuberculosis there.

Correspondence.

"Audi alteram partem."

ENCEPHALOMYELITIS FOLLOWING VACCINATION.

To the Editor of THE LANCET.

SIR,—The statement in the interesting letter by Dr. D. Hunter and Dr. W. R. Brain in your last issue (p. 1250), that their six cases of acute meningo-encephalomyelitis "differed clinically in many respects from acute epidemic encephalitis lethargica, and showed a marked clinical similarity to post-vaccinal encephalitis," would imply that this latter affection possesses a more or less stereotyped symptomatology. That has not been my impression, and I should say that only in the most general sense can any uniformity of symptoms in recorded case reports of post-vaccinal encephalitis be postulated. Without incurring the necessity of alluding to British experience which will shortly be available in a Government report, I may simply refer to Lucksch's analysis of clinical types observed in continental cases of post-vaccinal nervous disturbance. No fewer than six types are noted and I here append them. (1) Involvement of meninges only, so-called meningitis serosa. (2) Cases associated with headache, vomiting, convulsions, pareses, and somnolence without ocular palsies. (3) Like (2), but presenting trismus or tetanus-like symptoms. (4) Like (2), but presenting ocular symptoms, and consequently approaching closely to encephalitis lethargica. (5) More diffuse forms with bladder disturbances. (6) Cases showing cord involvement mainly, and simulating poliomyelitis anterior.

Unfortunately, in many cases clinical descriptions are meagre and entirely inadequate for purposes of accurate clinical filing. It is all the more necessary, therefore, that whenever opportunity occurs, clinical records should be amplified by careful autopsy and fullest investigation of the central nervous system from the the histological and experimental point of view. Much progress may be hoped from the investigation, on lines laid down by Dr. Hunter and Dr. Brain, of anomalous types of encephalomyelitis disseminata. At the present time, however, it is in my opinion unwise to assume that post-vaccinal nervous sequelæ conform to any very hard-and-fast clinical type. Hitherto, purely clinical investigation has helped little towards the elucidation of this serious sequela.

I am, Sir, yours faithfully,

J. C. G. LEDINGHAM.

Lister Institute, London, June 16th, 1928.

RECENT KNOWLEDGE OF HOOKWORM DISEASE.

To the Editor of THE LANCET.

SIR,—An editorial note to a letter of mine appearing in THE LANCET of May 19th (p. 1043) remarks that "we possess no convenient résumé in a single cover of the immense mass of recent knowledge regarding hookworm disease in various parts of the world." Commenting on this in your issue of June 16th (p. 1251) Dr. Carozzi draws attention to two publications which are evidently felt to fill the need. The first, the admirable Publication 11 of the Rockefeller Foundation, International Health Board, dated 1922, is an arranged bibliography of 5680 items, but without an index to the arrangement. It corresponds to the necessarily indigestible list of references at the end of a scientific paper, and not to the predigested summary which commonly precedes it and whose absence is clearly the matter on which you comment.

The second publication, from the International Labour Office, Dr. Carozzi believes to give a fairly complete account of the different aspects of the problem of ankylostomiasis. The first requisite of such an account is reliability. The International

Labour Office should conform to the International Laws of Zoological Nomenclature. The hookworms of man do not belong to the genus *Uncinaria*. Such designations as *Ankylostoma Dubini*, *A. Stiles*, and *Ankylostoma duodenale Dubini* (E. Perroncito) are lawless, and meaningless, or confusing. *A. duodenale* is said to have been studied by Perroncito and Railliet. The greatest name of all in this connexion is omitted, Looss, and the omission explains much. The figures given, after Perroncito, of the head end of this worm are inaccurate, and are perhaps composite figures of the two common hookworms of man, *Ancylostoma duodenale* and *Necator americanus*. Looss's drawings are unsurpassed in accuracy and artistic merit. Others, including possibly my own, follow the same line, but at an easily discernible artistic interval. At all events accurate figures are readily obtainable. That entitled "Female ankylostoma filled with eggs" actually depicts a small portion of one of the uteri. A table facilitating differentiation of the two parasites is attributed to me in 1919. I pointed out a few of these differences in 1913, but not in 1919; I do not believe that the others are correct. I claim, then, an established alibi at the time when this bastard with its embarrassing likeness to my own offspring was procreated. *A. duodenale* will not be found in the fæces if search be made for a pale, flesh-coloured, red worm. Regarding minute anatomy, the presence of the piercing teeth at the bottom of the oral cavity is unmentioned. Of the œsophagus it is said that it dilates into a muscular stomach, a statement taken from Perroncito. Of this Looss wrote 23 years ago that the description was incomprehensible. Its repetition to-day is less understandable than ever. Concerning eggs, and disregarding the slip which makes the breadth greater than the length, it is not the case that those of *A. duodenale* have a double-outlined shell, thicker and less fragile than those of *N. americanus*, that any difference in segmentation between those of the two species is discernible, that only a quarter of the eggs produced by hookworms are viable, or that their characteristic appearance prevents likelihood of confusion with those of other parasites. Nor is it the case that a saturated solution of sodium chloride preserves hookworm eggs for diagnosis, while Teleman's method of concentrating eggs for this purpose, advised in the article, has for many years been, apparently completely, abandoned as ineffective and as destructive of valuable microscopes. Culture does not necessarily reveal 99 per cent. of "carriers." It is stated that at least 20 million persons are infected. This is strictly true—but misleading, since 800 million is perhaps not an over-statement. And that being so, and there being, as I believe, no evidence that most infected persons can be dismissed as "carriers" and much to suggest that they cannot, it is regrettable that an article from an office of the League of Nations, and one dealing with so vital a subject, should fall so deplorably short of the admirable standard set, for example, by the League's publications on malaria which have forwarded knowledge in the most striking manner. I have not dealt with the whole article, but it follows, Sir, that my criticisms of it have not weakened the truth of the final sentence of my original letter or of your own comment thereupon.

I am, Sir, yours faithfully,

Ealing, June 16th, 1928. CLAYTON LANE.

A TREATMENT FOR HAY FEVER.

To the Editor of THE LANCET.

SIR,—I have had good results from a simple method of treating hay fever, which was evolved by experiment on myself. It consists in spraying the nostrils with a 1 per cent. solution of picric acid in water every day for about a fortnight before the onset of symptoms, and in giving grs. 3 of valerianate of zinc in a pill three times a day during the whole of the hay fever period. Cases which have not come under observation before the attack may be treated in the same way, but before using the picric acid it is necessary to reduce the swelling of the nasal mucosa by spraying with an adrenalin chloride solution, 1 in 1000. When picric acid is used for hay fever the spray should be a very fine one, practically a mist, and the patient instructed to keep the mouth wide open, and to breathe deeply during the process, thus preventing any of the solution from getting into the larynx. In one case, where I neglected this precaution, and was using rather a coarse spray, the patient had an attack of laryngeal spasm, and didn't like it. Considerable success has attended this treatment.

I am, Sir, yours faithfully,

Charmouth, Dorset, June 18th. T. PAGAN LOWE.

VARICOSE ULCERS: ULTRA-VIOLET LIGHT AND UNNA'S PASTE DRESSINGS.

To the Editor of THE LANCET.

SIR,—Dr. D. Colebrook's article on a comparison of treatment of varicose ulcers by ultra-violet light and Unna's paste, published in THE LANCET of May 5th, demands some comment.

1. From the addendum it is clear that most of the work was carried out with sub-erythema doses. In only 25 per cent. of the doses was the radiation equivalent to an erythema dose on normal skin. The number of doses with the water-cooled lamp was almost negligible, less than 10 per cent. It is not quite clear whether an attempt was made to treat the ulcerated surface, the edges of the ulcer, and the surrounding skin with different doses at the same time. 2. The frequency of treatment in the 31 light cases was as follows: 18 received less than two exposures a week, 4 were treated twice weekly, 7 between two and three (nearer two than three) times a week, and only 2 cases received three or more treatments per week. 3. Between exposures "no support other than that which the patient was in the habit of wearing" was allowed, so it follows that some of the ambulatory cases were permitted to walk about with no support for their distended veins.

The failure to heal ulcers with ultra-violet rays as given by Dr. Colebrook is not surprising. Surely even the greatest enthusiast has not attributed such potency to the rays, as to imagine that a varicose ulcer, possibly of many years duration, could be healed by a sub-erythema dose given less than twice a week. The work was undertaken because of the various claims for the value of ultra-violet rays in varicose ulcers. Dr. Schiller,[1] amongst others, has claimed good results, but there is little resemblance between his technique and that of Dr. Colebrook. Dr. Colebrook's suggestion that the ultra-violet treatment given by her played an unimportant part in the cases which did improve is correct, as the amount they had was negligible.

There is, moreover, a discrepancy between the first table on page 906 and the addendum. From the table it would appear that the worst ulcers were treated with Unna's paste; yet from the addendum it can be seen that the largest ulcer treated with light was so extensive that it covered three quarters of the whole leg, and was not measured. (Incidentally, this ulcer received 10 sub-erythema exposures in six weeks. Is it any wonder that it is reported as I.S.Q. at the end of six weeks? One would be glad to know whether Unna's paste was tried subsequently in this case, and with what result.) Also, the average size of the ulcers on radiation (it is true that only a portion of some may have been given light) was 22 sq. cm.; the average size of those treated by Unna's paste was 13 sq. cm.

It is not my purpose to decry the use of Unna's paste, but simply to demonstrate that from the published report no conclusions can be drawn as to the value of ultra-violet rays in varicose ulcers.

I am, Sir, yours faithfully,

London, W., June 9th, 1928. M. WEINBREN.

MEMORIAL TO DR. IRIS FOX.

To the Editor of THE LANCET.

SIR,—An opportunity arises in the proposed xtension of the pathological department of the oyal Free Hospital to erect a permanent memorial o Iris Fox, who gave her life in the course of her work n that department. We wish to raise a sufficient fund o build and equip a laboratory or library for research nd name it after Iris Fox. We believe that many of er friends and those whom she taught will welcome ne opportunity of contributing to this fund to erpetuate her memory. A letter from the medical chool has already been sent to past and present udents, explaining the need for the general extension f the pathological department. It is hoped that the resent communication may reach any who have been issed, and who would like their contribution to be evoted to the special Iris Fox Fund, as well as any her friends who would care to send a gift. Donations ould be made payable to the "Iris Fox Memorial und," and be sent to Miss Lorel Goodfellow, Hon. ecretary and Treasurer, Flat 3, 28, John-street, edford-row, London, W.C.1.

We are, Sir, yours faithfully,

FLORENCE E. BARRETT, HILDA M. HALLIDAY,
J. HENRY DIBLE, CLEMENT E. SHATTOCK,
HILDA FOX, H. WINIFRED STURGE,
LUCY WILLS.

June 13th, 1928.

*** The proposal is, we understand, to remodel the esent pathological block, which was built in 1914–15, nd to add a new wing to it. The present department, hich is very overcrowded, includes five qualified sistants working under the professor, some seven boratory attendants, and a group of 12 to 20 students. he most urgent need is for a biochemical laboratory, nt a new clinical laboratory is also required for udents to work on their clinical cases, as well as rther accommodation for research workers and for e training of assistants. It is also proposed to form small library of books for reference and current urnals, and to provide for the proper housing of cords.—ED. L.

OVARIAN HÆMORRHAGE.

To the Editor of THE LANCET.

SIR,—In reporting, on p. 1221 of your last issue, series of cases of ovarian hæmorrhage simulating ppendicitis, I briefly discussed the pathology of the ndition. My attention has since been drawn to r. Wilfred Shaw's[1] extensive observations on this bject, which make it clear that rupture of the aafian follicle is not (as I suggested) associated with eeding, and that the corpus luteum in its earliest ages is free from blood. His investigations show at hæmorrhage takes place during the stage of scularisation. and rarely also during involution; exaggeration under abnormal conditions is liable distend the follicle and produce urgent symptoms, in the cases described.

I am, Sir, yours faithfully,

Southend-on-Sea, June 19th, 1928. R. K. WILSON.

[1] Some Pathological Forms of Corpus Luteum. Jour. Obstet. Gynæc. Brit. Emp., 1927, xxxiv., 300; Ovulation in the man Ovary, its Mechanism and Anomalies. Ibid., p. 469.

A HOSPITAL FOR THE MIDDLE CLASSES.—Croxted use, West Dulwich, is being converted into a hospital of beds to be devoted solely to the needs of the middle classes. stands in grounds of between three and four acres, and es its inception to a small body of doctors and other fessional men resident in the district. It is to be called West Dulwich General Hospital and will be staffed inly by local medical men with the help of consultants. is expected that patients' payments will cover the greater t of the cost of maintenance: the balance will have to defrayed by voluntary subscriptions.

Obituary.

WILLIAM JAMES HOWARTH, C.B.E., M.D., CH.B. VICT., D.P.H.,

LATE MEDICAL OFFICER OF HEALTH TO THE CITY OF LONDON.

WE regret to announce the death of Dr. William James Howarth, until recently the medical officer of health to the City of London, which occurred on Friday, June 15th, in the sixtieth year of his age.

William James Howarth was educated at Manchester Grammar School and Owen's College. He graduated M.B., Ch.B. in 1891, and proceeded to the M.D. degree two years later. Having held resident appointments at the Manchester Royal Infirmary and at the Loughborough General Hospital, he decided to enter the public health service. He acquired the diploma of D.P.H. from the old Victoria University in 1896, and was immediately appointed medical officer of health for the borough of Bury. He held this post for two years, and was then for a brief time medical officer of health for the city of Derby and in 1908 was appointed medical officer of health and school medical officer for the county of Kent. He brought to his new post a high reputation as an administrator and this he justified in the very different atmosphere of a county health department. He developed health organisation in Kent on lines that were followed in many other areas, and there is no doubt that his work here led directly to his appointment as medical officer of health for the City of London in 1912 on the retirement of Dr. W. H. Collingridge. This post he held with distinguished success for 15 years, and his breakdown while still in middle life was a real loss to public health.

DR. W. J. HOWARTH.

Photograph by Elliott and Fry.

In connexion with the City of London Dr. Howarth necessarily held many important posts both in an active and an advisory capacity. He made his particular mark in connexion with food, and especially meat-supply, but he was an efficient officer over the whole range of his duties. He had a well-developed faculty of concentrating on the matter in hand and a clear-sighted vision which enabled him to determine what was the matter in hand. Shortly after being elected it became obvious to him that the work to which he could best devote his energies in London was that of meat inspection, which at that time, although carried out very well in a number of areas, was but indifferently done in a still larger number. The huge cattle market at Islington and the Central Meat Market at Smithfield afforded him an almost unparalleled field, of which he was prompt to take advantage. A quick worker and rapid thinker he soon mastered the problems set before him. In many instances these problems were merely those which he had met, on a smaller scale, in his earlier appointments, but his position in the City of London called for the issue of reasoned and authoritative judgments, which were duly forthcoming.

No one possessed a more intimate knowledge than he of butchers, their manners and customs, their likes and dislikes; very few officials were listened to by the butchering trade with more respect even on the somewhat thorny question of humane slaughtering. His Chadwick lectures on the Control of the Food-supply, quarries of information, were attended by crowded audiences, and the same occurred whenever he spoke in public on the Meat Regulations. On committees dealing with meat problems his services were of the first use; his work as a member of the Departmental Committee on Meat Inspection especially standing out. To the energy of this Committee are due the comprehensive Public Health Meat Regulations, 1924, which marked a decided step forward in the endeavour to secure cleanliness of the meat sold to the public, and Howarth helped to frame a scheme of meat inspection which is not only thorough but practical and workable. His reports to the Sanitary Committee of the City of London Corporation, always written after much careful observation and thought, left little more to be said, and his presence on deputations abroad to visit institutions dealing with the supply of food to this country was always welcomed by foreign colleagues to whom his knowledge and his attractive personality appealed. It is needless to say that at the Guildhall he possessed the complete confidence of the Corporation; he could rely on their support in dealing with many matters when health considerations involved difficulties for the city merchants. But while as a sanitarian he was quite fearless in dealing with the commercial community he spared no pains to be reasonable in his requirements.

The outbreak of war and the consequent depletion of his staff created many difficulties in the City health department. Howarth rose to the occasion and accepted the responsibility cheerfully which fell upon him as the chief rationing officer for London and the Home Counties. He worked unceasingly as a member of various departmental committees of the Ministry of Health and on the Board of Management of the Low Temperature Research Station at Cambridge, and the Milroy Lectures, which he delivered before the Royal College of Physicians of London in 1917 form a remarkable epitome of his multifarious knowledge on the subject. The three Lectures were published in full in THE LANCET, and to the last one there was appended a synopsis of the difficulties to be met with in the organisation of meat inspection at the time, and indications for placing that inspection on a more satisfactory basis. The future requirements were set out with a view to securing uniformity of action in a routine of meat inspection which could be made a compulsory duty on all urban sanitary authorities; the problems presented by boneless and canned meat and by imported carcasses were dealt with in particular detail, and the necessary regulations suggested for a system of meat-marking and for the investigation of the conditions in rural slaughter-houses. The lectures were exhaustive, and the lessons contained in them have been consistently applied.

There is no doubt that the years of the war tried Howarth's physical and mental capacities more than he would allow, but it was not in him to spare himself. In 1921 he was elected President of the Society of Medical Officers of Health, and worked hard in the interests of a Society with which he had for many years been conspicuously associated. But soon after the completion of his year of office his friends noticed the first signs of the insidious illness that caused his death. It became apparent that difficulties which he used to surmount with ease began to cause him needless worry. He had, moreover, to endure the death of his elder son at school, and was deeply affected by the tragedy. He could not, however, be persuaded to take the complete rest that he needed, and to this reluctance to give up work the abbreviation of his valuable career may be traced.

"My early recollections of Dr. Howarth," writes Sir William Hamer, "are of his work in a field of inquiry to which he was destined to give particular attention in the years to come, when he became medical officer of health of the City of London. In that capacity he had to advise regarding the food supplies of the London population, and he soon became *the* authority on questions concerning food, markets, cold storage, and the like; he was, moreover, always ready to impart knowledge and to give guidance and help to public health colleagues, who went into the City to discuss their difficulties with him; and such help was of special value, for from the first he strove to make the fullest possible use of the opportunities afforded him by the fact that he served an authority concerned with the greatest markets and the largest cold storage enterprises in the world. . . . As President of the Society of Medical Officers of Health he won golden opinions from all, by his courtesy, kindness, impartiality, straightforwardness, and spirit of comradeship. It fell to my lot in April, 1923, speaking on behalf of the Metropolitan Branch, to ask the president of the Society, Dr. T. Eustace Hill, to accept a portrait of Dr. W. J. Howarth, to be added to the gallery of portraits of past presidents. I remember well how the kindliness and consideration I had invariably experienced at his hands prompted me to apply to him one of the few Latin quotations at my command, and to say that Dr. Howarth's faithful study of honourable arts had beautified his character and made him incapable of any harshness of manner. I recollect, too, that an authority on poetry, and on Latin poetry too, who happened to be present on the occasion, assured me that the quotation was most appropriate. . . . Dr. Howarth and I began our work as medical officers of the City Corporation and of the London County Council respectively in the same year, 1912, and naturally and inevitably followed the tradition of close coöperation which had been firmly established by William Collingridge and Shirley Murphy. Throughout the years of our service we travelled westwards, as Carlyle has it in his 'Life of John Sterling,' 'except in opinion not disagreeing'; though, indeed, even in opinion there was not, so far as I know, upon any matter of importance a pin to choose between us. In committee work and at conferences of medical officers of health and other gatherings, Dr. Howarth had ever in mind the interests which his great predecessor Sir John Simon spoke of as those, of the millions of population under the ravages of infectious disease, who were themselves only dimly conscious of having any interests. By-laws, General Powers Acts, tuberculosis schemes, whatever the question chanced to be, Dr. Howarth was always ready to lend a hand and do anything in his power to bring about improvement in the health of London as a whole; always having the grace to use his powers 'as ever in the great Taskmaster's eye.'"

Dr. W. G. Willoughby writes: "In William James Howarth the profession has lost a member who was instinct with the dignity of his calling, filled with the principles and practice of medicine and laudably ambitious that no path which might lead to the general welfare as objective be left unexplored. His activities ranged over the subjects ancillary to the public health branch of the profession to which he gave his best years, but especially he was devoted to preventive medicine whether on the practical, ethical, educational, or scientific side. His aim appeared to be a complete grasp of this worthiest of subjects, elusive though it must of necessity be, while at the same time his great powers of administration sought and found expression in many spheres. In chatting with him small but knotty points, one remembers his incisive settling first of the principles on which all detail must depend; the many with whom his activities in the medical societies in which he was associate or some time ruler must have experienced the benefits of his full grasp of a subject whether in laying out a thesis for debate or in constructive criticism."

Dr. Howarth leaves a widow, a son, and a daughter, and general sympathy will be extended to them in their loss. Mrs. Howarth had been a valuable ally in all his undertakings and nursed her husband devotedly through his long illness.

JOHN AYMERS MACDOUGALL, M.D., F.R.C.S.ED.

Dr. John A. MacDougall died on June 12th at Salerno, Midlothian, aged 84 years. He was the son of Dr. George MacDougall, of Galashiels, and was educated at Edinburgh High School and University, where he qualified in 1865, becoming house surgeon in 1866 to Prof. James Spence. Dr. MacDougall practised in Galashiels until 1875, when he took the F.R.C.S. Edin. and proceeded to Carlisle, where he became surgeon to the Cumberland Infirmary while still engaged in general practice. Ten years later his health made it desirable that he should spend the winters abroad, and he decided to settle on the French Riviera. He practised in Cannes for 29 years, became Officer de Santé at Marseilles in 1890, and later acted as consulting surgeon to the Queen Victoria Memorial Hospital at Nice. In 1914 he retired from active work and returned to Scotland. Dr. MacDougall was a keen and efficient surgeon and a good diagnostician. His services were in demand all over the Riviera, and he inspired not only confidence but friendship in his patients.

Dr. A. Logan Turner writes of him: "John MacDougall possessed in an exceptional degree the clinical instinct. He was an accurate observer and he seldom made a mistake in diagnosis. 'Doing justly, loving mercy, and walking humbly,' he was a man greatly respected by the friends whom he attracted by his integrity of character, his great personal charm, and his obvious sincerity. During his retirement the periodic visits paid to him by his old associates were always a source of gratification to him. Gifted with an excellent and accurate memory he delighted in recalling the events of bygone days, and his reminiscences of the Edinburgh Medical School of 50 years ago were always interesting and instructive. As a dresser he came into close touch with James Syme, for whom he retained throughout his life a profound admiration, and whose teaching and practice of surgery he closely followed in after years. Joseph Lister during this period was working in Glasgow, and although he did not publish until 1867 his first series of cases of compound fracture treated by the new method based on the 'Germ theory' of Pasteur, rumours of his work were already filtering through to Edinburgh. To the end of his life MacDougall kept himself abreast of the modern developments in medicine and surgery, and, just prior to his death, had begun to prepare for publication his recollections of James Syme."

Dr. MacDougall leaves a widow and daughters.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments have been notified: Surg. Cmdrs. G. H. Hayes to *Barham* (on recommg.); G. Carlisle to *Victory*, for R.N. Hospl., Haslar; H. F. Briggs to *Kent*, on commg.; and D. H. C. Given to *Tamar*, for Singapore Naval Base, as medical officer in charge of medical organisation and as Naval Health Officer.

Surg. Lts. C. H. Egan to *Barham*; J. Hamilton to *Kent*, on commg.; E. T. S. Rudd to *Victory*, for R.N. Barracks, Portsmouth, temp.; W. P. E. McIntyre to *Vivid*, for Plymouth Hospl.; and W. G. C. Fitzpatrick to *Bee*; A. E. Phillips to *Titania* (on relief); W. W. Darley to *Emperor of India*; and T. L. J. Barry to *Magnolia*.

ROYAL ARMY MEDICAL CORPS.

ARMY DENTAL CORPS.

Temp. Capt. W. Wormington, Dental Surg., Gen. List, to be Capt.

Temp. Lt. S. D. Badman, Dental Surg., Gen. List, to be Lt.

The undermentioned to be Lts. on prob.: J. A. O'Connor, R. Wall, H. L. Foulkes-Roberts, and H. S. Golding.

SUPPLEMENTARY RESERVE OF OFFICERS.

Lt. F. W. Oldershaw to be Capt.

TERRITORIAL ARMY.

Capt. J. D. M. Cardell resigns his commn.

Lt. D. T. McDonald (late Northumberland Fus.) to be Lt.

Lt. H. Miller to be Capt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. A. F. G. Guinness, from the Active List, to be Capt.

Lt. J. W. Murdoch, from Active List, to be Lt.

General Hospitals: Maj. T. H. W. Alexander having attained the age limit relinquishes his commn, and retains his rank.

ROYAL AIR FORCE.

Ft. Lt. J. A. Perdrau relinquishes his temporary commission on completion of service and is permitted to retain his rank.

Temp. Capt. A. H. Mills (Dental Surgeon, General List) is granted a temporary commission as a Flight Lt. on attachment to the R.A.F.

Temp. Lt. H. D. Humphreys (Dental Surgeon, General List) is granted a temporary commission as a Flying Officer on attachment to the R.A.F.

INDIAN MEDICAL SERVICE.

Amar Nath Malhotra to be Temp. Lt.

Parliamentary Intelligence.

HOUSE OF LORDS.

THURSDAY, JUNE 14TH.

National Insurance Bill.

THE National Health Insurance Bill passed through Committee without amendment.

MONDAY, JUNE 18TH.

Government and the Deaf and Dumb.

Lord CHARNWOOD called attention to the position in industry of the congenitally deaf and dumb and of those who were wholly or partially deafened in later life by disease or accident, and to the limitations of the present provision made for their training and for securing employment for them; and asked His Majesty's Government whether they would (by means of an Inter-Departmental Committee or otherwise) inquire into the whole matter.

Viscount GAGE, replying for the Ministry of Health, said that before the Ministry came into existence a great deal of the work on behalf of the deaf and dumb was done by voluntary associations whose work was still being continued, and the Minister had no intention of interfering with their magnificent work. If they were going to apply the analogy of the machinery set up to deal with the blind to all congenital afflictions, the Ministry would have a great financial load placed upon them. The information of the Board of Education went to show that deaf children who had attended special schools provided by the Board up to the age of 16 were able to obtain and retain reasonably good and remunerative employment.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 13TH.

R.A.M.C. Quartermasters as Pharmacists.

Sir WILFRID SUGDEN asked the Secretary of State for War how many quartermasters of the Royal Army Medical Corps (Territorial Army) possess the qualification of pharmacist; and whether offers from qualified pharmacists of their services in this capacity would be considered by the Army medical authorities.—Mr. DUFF-COOPER replied: None of the quartermasters at present in the Royal Army Medical Corps (Territorial Army) possesses the qualification of pharmacist. If a qualified pharmacist were recommended for appointment as quartermaster his claim would gladly be considered by the War Office. But at present there are no vacancies for such appointments.

Dispensers in the Territorial Army.

Sir WILFRID SUGDEN asked the Secretary of State for War how many dispensers in the Territorial Army held the qualification of pharmacist, and what advantage such dispensers enjoyed as regards rank over dispensers not possessing the qualification of pharmacist.—Mr. DUFF-COOPER replied: None, sir.

Tuberculosis among Members of Defence Forces.

Dr. VERNON DAVIES asked the Prime Minister what steps, if any, were being taken to examine into the question of the attributability of pulmonary tuberculosis in the defence forces to the conditions of service.—Mr. BALDWIN replied: Investigations are being made by a Committee composed of medical members of the Service departments, whose recommendations on the subject have not yet been received.

Medical Cost Accounts for Defence Forces.

Dr. VERNON DAVIES asked the Prime Minister what steps, if any, were being taken to establish a common system of costing for the medical services of the Army, Navy, and Air Force, respectively, particularly with regard to hospitals. —Mr. A. M. SAMUEL, Financial Secretary to the Treasury, replied: Cost accounts, in a common form, have been compiled for a period of three months at one Naval, one Military, and one Air Force hospital. Those accounts have been under the consideration of the Joint Medical Services Committee of the three departments. But it has not yet been decided what modifications would require to be made in the common form before it would be suitable for general adoption.

Medical Examination of Emigrants to Canada.

Mr. HASLAM asked the Secretary of State for Dominion Affairs if he could now give the number of persons rejected by the Canadian doctors as unfit for emigration to Canada from Jan. 1st to April 30th, and the number of persons who, though requested to present themselves for medical examination, gave distance, inconvenience, or expense as a reason for their inability to attend; and whether he had any evidence that these examinations were hindering emigration.—Mr. AMERY replied: The number of persons rejected by the Canadian Government doctors between Jan. 1st and April 30th was 1740. There is no record of the numbers who gave distance, inconvenience, or expense as a reason for their inability to attend. I am not prepared at present to express any opinion as to how far the new system is hindering the movement from this country, but I invite my hon. friend's attention to the report of the Immigration Committee of the Canadian House of Commons, a telegraphic summary of which appeared in the *Times* of June 8th. That report, whilst making certain recommendations for improving the new system and obviating inconveniences in remote districts, does not admit that the new system has reduced the volume of British immigration into Canada.

THURSDAY, JUNE 14TH.

Hospital Officers in the Prison Service.

Mr. ERNEST BROWN asked the Home Secretary the number of hospital officers, male and female, in the prison service; how many, in each case, were registered by the General Nursing Council as ordinary nurses or as mental nurses; and at what prisons, if any, were hospital principal officers appointed who had not qualified for State registration.—Sir WILLIAM JOYNSON-HICKS replied: There are 130 men hospital officers and 10 women hospital officers in the prison service; of the men 38 are registered by the General Nursing Council as nurses, 9 as mental nurses, and 6 are registered under both heads; none of the women are registered. There are, however, 33 fully trained women nurses employed in the prison service, all of whom are State registered, 31 being on the general register and 2 on the register of mental nurses. At the following prisons the hospital principal officer is not registered:—Men: Birmingham, Brixton, Liverpool, Manchester, Parkhurst, Wandsworth, Wormwood Scrubbs. Women: Liverpool, Manchester, and Portland Borstal Institution.

Dr. Voronoff's Visit to England.

Mr. BRIANT asked the Home Secretary if a permit had been given to Dr. Voronoff to visit this country; if so, for what period was is it available; and if such permit would allow him to carry out experiments of the nature of grafting on human beings.—Sir W. JOYNSON-HICKS replied: Dr. Voronoff was given leave to land in the United Kingdom on May 22nd and no time-limit was imposed. His object was to give certain lectures at Cambridge University and elsewhere, but no licence of any kind has been given him to experiment in this country.

Mr. BRIANT asked if Dr. Voronoff could experiment without a licence? The British public were extremely anxious to know that he should not have an opportunity of conducting dangerous and disgusting operations which included the transfer of the organs of propagation from an ape to a woman.

Sir W. JOYNSON-HICKS: It is quite impossible that he should conduct any experiment involving vivisection or cutting operations on any animal without a licence, and that licence I have not granted and do not propose to grant. (Cheers.)

Lieut.-Colonel FREMANTLE asked if a human being was no an exception, and if he could not offer himself for experimen if he liked?

Mr. RADFORD asked if it would be possible for some othe licensed person to make an operation on an animal an leave it to Dr. Voronoff to complete the experiment on human being. Did the Home Secretary note that it wa a violation of everything that was decent in our constitutio that this man should be allowed to conduct such experi ments in this country?

Sir W. JOYNSON-HICKS: My hon. friend is really no right. No such experiments are conducted in this countr at all, and the suggestion that it will be possible to hav an operator who has a licence will not work, because I an most careful to inquire into the nature of the operation conducted under a licence.

Slum Clearance Schemes.

Mr. DAY asked the Minister of Health how many scheme for the purpose of slum clearance were now in operation i Great Britain; how many of these had been authorised and the number of houses and families, and the total numbe of persons, who would be affected.—Mr. CHAMBERLAI replied: 113 slum clearance schemes, affecting approximatel 14,000 properties, have been confirmed since 1919 in respec of areas in England and Wales. The number of person required to be rehoused under these schemes is 66,968. Th available statistics do not show how many families ar involved. With regard to Scotland, I would suggest tha the hon. Member should address a similar question to m right hon. friend the Secretary of State.

Use of Croton Oil in Mental Hospitals.

Mr. CHARLETON asked the Minister of Health whethe the recommendations made by the Royal Commission o Lunacy and Mental Disorder, 1926, for the control of th use of croton oil, whether for medicinal or punitive purposes in mental institutions were receiving his attention; an whether he proposed to take any administrative or othe action to deal with this matter.—Mr. CHAMBERLAIN replied The recommendation of the Royal Commission has receive consideration, but the report does not support the suggestio made in the question that the drug is used for punitiv purposes. The administration of drugs of this character i the subject of frequent consultation between the Medica Commissioners of the Board of Control and the medica officers of mental hospitals, and I am advised that no furthe action is at present necessary.

Contributory Pensions and Mentally Deficient Children.

Mr. LAWSON asked the Minister of Health if he wa aware that the mother of a child who had reached 14 year of age was deprived of its allowance under the Widows Orphans', and Old Age Contributory Pensions Act althoug the child had been for some years excluded from schoo owing to its mental condition; and whether he was prepare to amend the Act so that a child who was medically certifie as mentally deficient could continue to receive the benefi of the allowance beyond the age of 14 years.—Mr CHAMBERLAIN replied: The answer to the first part of th question is in the affirmative. As regards the second part I would point out that an amendment which would hav secured what is now proposed was negatived when the Bi was in Committee, and I remain of the opinion that it woul not be appropriate to make specific provision for thi exceptional class in the contributory pensions scheme.

Sulphur Dioxide in the Milling of Barley.

Mr. WESTWOOD asked the Parliamentary Secretary t the Ministry of Health if he had received a communicatio from Messrs. James Proctor and Sons, Limited, barley millers, Liverpool, offering documentary evidence that th Ministry of Health (Food Preservatives) Regulations, i their application to the use of sulphur dioxide in th bleaching and preserving of barley, had completely stoppe their trade, and that their previous buyers had placed thei orders with foreign firms; and if he was aware that regula tions prohibiting the use of sulphur dioxide in the milling o barley were at one time enforced in Germany and America and in both countries had been withdrawn because of thei impracticability; and would he be prepared to meet deputation of millers to discuss the effects of these regula tions on the barley milling trade in England and Scotland.— Mr. CHAMBERLAIN replied: I have received the communica tion referred to in the first part of the question. I am awar that the use of sulphur dioxide in the milling of barley i at present permitted in Germany and the United States o America, but I have no information to show that th prohibition of its use in those countries was attempted an abandoned because it is impracticable. The fact tha exporters of barley to this country are able to comply wit our regulations scarcely bears out that suggestion. A regards the last part of the question I would remind th

hon. Member that two deputations from the barley trade have already been received and that full consideration has been given to their representations. I do not think that any useful purpose would be served by the reception of a third deputation.

Poison Gas and Bacteria in Warfare.

Sir ROBERT HUTCHISON asked the Prime Minister whether, in view of the recommendation of the League of Nations Disarmament Commission that all subsidies, both to private and official laboratories promoting research in poison gases, should be abolished, he could say which nations had adopted these recommendations; what action the British Government had taken; whether any subsidies were now being paid to manufacturers of poison gases and bacteria; and, if so, to whom these subsidies were being paid and the amount in each case.—Mr. BALDWIN replied: Certain classes in regard to chemical warfare were included in the text of the Draft Convention drawn up by the Preparatory Commission for the Disarmament Conference at its third session, but they have not yet come forward for discussion on the Preparatory Commission. The answer to the third part of the question is in the negative.

Washington Hours Convention.

Mr. RILEY asked the Minister of Labour the names of the countries which had already unconditionally ratified the Washington Hours Convention and the names of the countries which had decided to ratify conditionally on ratification by Great Britain and certain other countries.—Sir ARTHUR STEEL-MAITLAND replied: According to my information Belgium, Bulgaria, Chile, Czecho-Slovakia, Greece, India, Luxembourg, and Roumania have ratified the Washington Hours Convention unconditionally, and Austria, France, Italy, and Latvia conditionally on ratification by Great Britain and other countries.

Deaths of Women in Childbirth.

Mr. TASKER asked the Minister of Health the percentage of deaths of mothers at childbirth where doctors attended the birth of children with uncertificated midwives in attendance; and what was the percentage of deaths of mothers at childbirth when attended by certificated midwives only.—Mr. CHAMBERLAIN replied: No complete statistics are available on these points. As regards the last part of the question I may refer the hon. Member to p. 42 of the recent report issued by my department on the "Protection of Motherhood," on which is a summary of the results of an analysis of the midwifery work of the Queen Victoria Jubilee Institute over a period of years.

Treatment of Pensioners with Chronic Disabilities.

Mr. DUCKWORTH asked the Minister of Pensions whether, seeing that many ex-Service pensioners suffering from chronic disabilities were now being referred to national health insurance for treatment, he would reconsider this decision and grant institutional treatment and allowances, in view of the hardships suffered by such pensioners.—Major TRYON replied: It is the duty of the proper medical officers of the Ministry to prescribe whatever form of treatment they may consider necessary, and in a case where no special treatment beyond attention from a general practitioner is required, the pensioner is advised to consult the practitioner whose services are available to him under the Health Insurance Acts. This is the long-standing practice of the Ministry, and I should not be justified in requiring, as the hon. Member suggests, the provision of hospital treatment in all cases regardless of medical views as to whether such treatment is necessary or not.

Board of Survey and Naval Invaliding Cases.

Mr. HORE-BELISHA asked the First Lord of the Admiralty in how many cases in the last 12 months the Board of Admiralty had overruled the recommendations of the Board of Survey in invaliding cases, and in how many cases had they overruled the decision of the commander-in-chief.—Lieut.-Colonel HEADLAM, Parliamentary Secretary to the Admiralty, replied: In 52 cases of invalidings during the year ended Dec. 31st, 1927, the opinion of the Board of Survey that the cause of invaliding was not attributable has been overruled. In no case was an award of attributability altered. No special recommendations were made by commanders-in-chief.

MONDAY, JUNE 18TH.

Medical Inspections of Emigrants to Canada.

Sir ROBERT THOMAS asked the Secretary of State for Dominion Affairs whether he was aware that there were widespread complaints, both here and in Canada, that the new system of medical inspection had antagonised the British medical profession and created an atmosphere unfavourable to emigration to Canada; and whether he would discuss this with the Dominion Government.—Mr. AMERY replied: I have seen press statements of the kind to which the hon. member refers, but I am not prepared, at present, to express any opinion as to the effect of the new system of medical inspection on the movement from this country. From the latest information in the press I gather that it is proposed materially to modify the new system.

Medical Inspection of Casual Paupers.

Mr. SHEPHERD asked the Minister of Health whether he would instruct boards of guardians to arrange for the medical inspection of casuals to be carried out in the evening before the risk of infection of clothes and bedding had been incurred, and also in order that men might be released early in the morning, and thus be given time to search for employment en route for the next casual ward.—Mr. CHAMBERLAIN replied: I am afraid that the varying conditions of staff and accommodation in the different casual wards, and the late hour of arrival of some casuals, make it impracticable to arrange that effect should be given to the hon. Member's suggestion.

Houses in Unhealthy Areas.

Viscountess ASTOR asked the Minister of Health the total number of houses demolished in unhealthy areas under improvement schemes since 1919; the number of persons displaced by reason of such clearances and since re-housed in new dwellings, and the number of improvement schemes completed.—Sir KINGSLEY WOOD replied: Up to March 31st last, the latest date for which figures are available, the number of properties demolished in pursuance of slum clearance schemes, confirmed since 1919 in respect of areas in England and Wales, was 4,841, out of 13,494 properties included in such schemes. Information as to the number of persons so far displaced by reason of these schemes is not available, but it is a requirement of the schemes that re-housing accommodation shall be provided for 65,180 persons. Up to March 31st last, 6164 new dwellings had been completed for this purpose, and a further number were in course of erection. Fifteen schemes have been fully completed and others are nearing completion.

Expenditure on Out-Relief.

Mr. THOMAS GRIFFITHS asked the Minister of Health the expenditure in England and Wales in 1926–27 and 1927–28 respectively, on out-relief to children boarded out, to persons ordinarily employed, and on other out-relief, in continuation of the 1925–26 figures for these items shown in Table 7 of the Annual Taxation Returns, Part I., 1925–26.—Sir KINGSLEY WOOD replied: The following is the information asked for: The expenditure by poor-law authorities in England and Wales in the financial year 1926–27 on out-relief to children boarded out was £251,432; to persons ordinarily employed and their dependents £15,001,350, and on other out-relief £8,661,227. The annual returns for the year 1927–28 have not yet been received, but the approximate amount spent on out-relief in that year to persons ordinarily employed (and their dependents) was £6,920,000, and on all other out-relief £8,163,000.

TUESDAY, JUNE 19TH.

Cost of Tuberculosis Treatment.

Mr. OLIVER asked the Minister of Health whether he could give the total annual cost to the nation of tuberculosis for the past four years, taken separately, and the amount of money expended during the same periods on the disposal or reclamation of slum areas.—Captain MARGESSON replied: The total expenditure in England and Wales on the carrying out of the approved schemes for the treatment of tuberculosis during each of the last four years for which figures are at present available, excluding capital expenditure, was as follows:—

Year ended March 31st—	£		£
1924	2,884,062	1926	3,157,694
1925	3,034,600	1927	3,294,991

I regret that similar information as regards slum clearance schemes is not at present available. Of the total estimated capital expenditure of £8,546,000 to be incurred on schemes which have been approved in recent years, it is estimated that about £4,551,000 has been expended to date.

QUEEN'S HOSPITAL FOR CHILDREN.—At a dinner at the Mansion House last week in support of the appeal for £100,000 for the extension of this hospital in the Hackney-road, the Duke of York, the President, pointed out that the institution deals with a larger number of cases than any other children's hospital in the kingdom. When the enlargements were originally proposed, on the eve of the war, the average annual attendance of children exceeded 80,000; it is now 147,000.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A meeting of the Council of the Royal College of Surgeons was held on June 14th, Sir Berkeley Moynihan, the President, in the chair. The following examiners were elected for the under-mentioned examinations :—

Primary Fellowship.—(Anatomy) Mr. P. N. B. Odgers.
First Conjoint.—(Anatomy) Prof. William Wright and Mr. R. Bramble Green ; (Physiology) Prof. E. B. Verney.
Dental Surgery.—Mr. A. T. Pitts and Mr. E. B. Dowsett (re-elected for a period of five years).

As the result of the Final Fellowship Examination for the Fellowship, held from May 17th to 31st, for which 115 candidates presented themselves, 34 candidates (32 men and 2 women) were approved. The following are the names and medical schools of the successful candidates upon whom the Council conferred the diploma of Fellow :—

A. J. W. Ahern, Melbourne and Guy's ; F. G. Allan, St. Thomas's ; J. C. Anderson, St. Andrew's and Sheffield ; L. H. Ball, Melbourne and Guy's ; J. Brumwell, Durham ; J. Carver, Cork and London ; A. M. Chaudhuri, Calcutta and St. Bart.'s ; F. M. Collins, King's Coll., Cambridge, and St. Bart.'s ; J. Elgood, St. Bart.'s ; D. M. B. Evans, Cardiff and Charing Cross ; C. W. Flemming, Oxford and Univ. Coll. ; W. R. Forster, Melbourne and St. Bart.'s ; A. C. Gairdner, Oxford and London ; J. Gray, Cambridge and Guy's ; W. A. Gray, Edinburgh, London, and Charing Cross ; P. Hack, Guy's ; A. F. Hobbs, Adelaide and London ; A. Hobson, Birmingham ; E. Holmes, Leeds ; G. H. Howells, St. Thomas's ; H. Jackson, Middlesex ; J. A. James, Bristol, Guy's, and London ; T. G. I. James, Cardiff and Guy's ; L. C. Lancaster, Cambridge and St. George's ; L. E. Le Souef, Melbourne and London ; A. C. MacLeod, Middlesex ; Gladys Helen Marchant, Calcutta and Royal Free ; M. G. Nimatallah, Cairo and London ; D. W. C. Northfield, Guy's ; Constance Mary Ottley, Oxford and London ; S. M. Power, London ; B. G. Scholefield, Oxford and Guy's ; J. H. Thompson, Univ. Coll. ; and J. H. M. Walker, Univ. Coll.

The diploma of Fellow was also conferred upon three candidates who have previously passed the examination and have now attained the required age of 25 years :—

James Gore, Birmingham and London ; R. L. Holt, Manchester ; and F. T. Ridley, Birmingham.

The diploma of Member was conferred upon the following who have passed the requisite examinations and have now complied with the by-laws :—

D. W. Currie, Leeds ; Yetta Gimpelson, Royal Free and St. Mary's ; Bhavani Natarajan, Bombay ; Margaret E. Peaker, King's Coll. ; Edith J. L. Smith, Royal Free ; G. N. Unnithan, Madras and Univ. Coll. ; and Elsie E. Wright, Royal Free and St. Mary's.

At the Primary Examination for the Fellowship, just completed, 160 candidates presented themselves, of whom 50 were approved. The following are the names and medical schools of the successful candidates :—

R. L. Almond, Melbourne ; M. I. Ashmawi, Cairo and St. Mary's ; M. Backwell, Leeds and Middlesex ; J. S. Batchelor, New Zealand and Guy's ; W. D. Bedford, Leeds ; H. S. Billcliff, New Zealand, St. Mary's, and Middlesex ; J. D. H. Bird, King's Coll. ; D. A. S. Blair, Cambridge and St. Thomas's ; H. A. Brittain, Dublin and Middlesex ; R. C. Brock, Guy's ; T. E. Cawthorne, King's Coll. ; H. L. Cleave, Bristol and Middlesex ; J. H. Cramsie, Sydney and Middlesex ; J. Dawson, Glasgow, St. Mary's, and London ; D. N. Eppstein, New Zealand ; R. H. Fish, Cambridge and St. Thomas's ; R. L. Flett, New Zealand and Middlesex ; J. F. E. Gillam, St. Thomas's and Middlesex ; Augusta G. Harrison, King's Coll. ; E. S. Harverson, Univ. Coll. ; H. P. Himsworth, Univ. Coll. ; M. B. Lavery, Belfast and Sheffield ; E. S. Lee, King's Coll. ; R. O. Lee, Cambridge and St. Thomas's ; W. Leslie, Guy's ; A. C. Lysaght, Bristol and Guy's ; R. G. Maliphant, Univ. Coll. and King's Coll. ; A. J. Mason, Otago, Middlesex, and St. Mary's ; M. V. Modi, Bombay and London ; H. S. Morton, Dalhousie and London ; A. R. Mowlem, Otago, St. Mary's, and Middlesex ; J. H. Mulligan, Aberdeen ; G. H. Newns, King's Coll. ; C. W. Olsen, Michigan and St. Bart.'s ; M. D. Patel, Bombay, London, and King's Coll. ; J. B. Pennybacker, Tennessee and Edinburgh ; P. N. Ray, Calcutta and St. Bart.'s ; J. G. Reid, Oxford and St. George's ; A. H. Richardson, Birmingham ; N. H. L. Ridley, Cambridge, St. Mary's, and St. Thomas's ; M. C. Rous, Cape and London ; A. Simpson-Smith, Cambridge and Guy's ; G. J. Sophian, St. Bart.'s and London ; V. Srinivasan, Madras and Middlesex ; F. S. Tait, Birmingham and Middlesex ; H. S. Thomas, Melbourne and Middlesex ; T. F. Todd, Guy's ; C. K. Vartan, St. Bart.'s ; A. L. Webb, Adelaide, Middlesex, and London ; and T. H. Wilson, St. Thomas's.

MILLION BEQUEST TO HOSPITAL.—The late Mrs. Mary Anne Fitzgerald, widow of a wealthy Englishman, has bequeathed £1,000,000 to St. Luke's Hospital, New York, for the construction of a new hospital overlooking the Hudson, as a memorial to Eli White, Mrs. Fitzgerald's father.

SOCIETY FOR THE STUDY OF INEBRIETY.—At a meeting to be held at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Tuesday, July 10th, at 4 P.M., Dr. H. M. Vernon will open a discussion on the Scientific Control of Alcoholism.

LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.—The prizes and certificates will be given away by Dr. Arthur Phear, at 8, Hunter-street, W.C., on Thursday, June 28th, at 4 P.M. Sir Francis Acland will unveil a Memorial Porch which has been erected in the north-east of the quadrangle.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the monthly meeting of the Faculty, held on June 4th, the following were admitted (after examination) as Fellows : Dr. John Craw, Whitehaven ; Dr. Suryakant Bhanshankar Trivedi, India ; and Dr. Andrew Morton Young, Taranaki, New Zealand.

CENTRAL ASSOCIATION FOR MENTAL WELFARE.—This Association, whose address is 24, Buckingham Palace-road, S.W., has arranged a course for persons engaged in the training of mental defectives, to be held in London from Sept. 8th to 29th. A syllabus, together with forms of application, may be had from the hon. secretary.

THE Minister of Health has appointed Lord Blanesburgh to be chairman of the Advisory Committee on the Welfare of the Blind, in succession to the late Mr. G. H. Roberts. The Committee advises the Minister on matters relating to the care and supervision of the blind, including any question that may be specially referred to them by the Minister.

ROYAL SANITARY INSTITUTE.—The annual congress and health exhibition will be held at Plymouth from July 16th to 21st, under the presidency of Viscount Astor.—A complimentary dinner to the retiring secretary, Mr. White Wallis, who has held office for nearly 48 years, is to be held at the Café Royal, Regent-street, London, on June 27th, at 7.15 for 7.30 P.M.

IMMUNISATION AGAINST DIPHTHERIA.—After considerable debate the Manchester City Council, on June 6th, decided by a large majority to promote a scheme for providing voluntary immunisation against diphtheria in Manchester Schools. Although the case-mortality has fallen, the incidence of the disease continues to increase, and about 70 deaths occur annually in Manchester from this disease. The public health committee's scheme involves the provision of toxoid-antitoxin gratis for six months to medical officers of the public health services and to private practitioners.

AUSTRIAN SPAS.—The Austrian State Publishing Office (Österreichische Staatsdruckerei), Wein I., Seilerstrasse 24, has published in the German language a reference book on "Austrian Spas," which is obtainable direct, or through any bookseller. The information contains much information of value to doctors concerning the various spas, the composition of their mineral waters and their therapeutical effects. The book has been compiled by well-known Austrian authorities, such as the University Professor, Dr. Viktor Conrad, Dr. Karl Diem, Ing. Dr. Josef Knett, Prof. Dr. Hans Horst Meyer, and Dr. Siegfried Stockmayer.

ADDRESS TO PROF. SYDNEY YOUNG.—On June 15th, at Trinity College, Dublin, an address signed by some 200 chemists in many parts of the world was presented to Prof. Sydney Young, F.R.S., who is retiring from the chair of chemistry in the University of Dublin, which he has held since 1903. Mr. W. F. Adeney, Prof. E. A. Werner, and Prof. F. E. Hackett spoke of Prof. Young's discoveries in the chemistry of distillation and of the accuracy of all his work. Mr. E. S. Gwynn, Provost of Trinity College, spoke enthusiastically of his work as a teacher in the College for the last 25 years, and Prof. Young expressed his appreciation of the honour paid to him, wishing his successor as much happiness in Trinity College as he had had himself.

WELSH BOARD OF HEALTH.—The Minister of Health has approved the following arrangements for the organisation and conduct of the work of the Board, which will henceforth consist of three members—Mr. John Rowland, Dr. Llewellyn Williams, Mr. Howell E. James. Mr. Rowland and Dr. Llewellyn Williams will continue to exercise the functions heretofore assigned to them as Deputy Controller of Insurance and Medical Member of the Board respectively. Mr. Rowland will preside at Board meetings, and will succeed Sir Thomas Hughes as Deputy for the Welsh member of the National Health Insurance Joint Committee. Mr. Howell James will become a member of the Board, and will cease to be secretary and ex-officio member of the Board.

The Gold Medal for the best candidate for entry as Dental Officer in the Royal Navy has been awarded to Surg.-Lieutenant D. W. Holgate.

THE Oxford University Press will shortly publish an English translation, with the author's latest additions, of Dr. v. Economo's "Cellular Structure of the Cerebral Cortex," the French edition of which we reviewed last week (p. 1230).

KING'S COLLEGE HOSPITAL.—In opening the annual fête at this hospital last week the Duchess of Portland said that it had been decided to take an additional house for the accommodation of nurses and to use an empty ward for child patients.

IRISH MEDICAL ASSOCIATION.—The annual meeting of this Association was held at Dublin on June 13th, the President, Dr. H. T. Warnock, in the chair. The annual report stated that on Dec. 31st, 1927, there was a membership of 390. There was a satisfactory balance in hand, but outstanding arrears amounted to over £900. The council for 1928–29 consists of the President (Dr. Warnock), the Vice-President (Mr. P. E. Hayden), and 26 representatives.

ROYAL MEDICAL BENEVOLENT FUND OF IRELAND.—The annual meeting of this Fund was held at Dublin on June 13th, with Mr. R. A. Stoney in the chair. It was reported that the number of grants made during the year had risen from 81 to 90, the amount disbursed in grants being £2071. The committee draws attention to the inadequacy of its funds to meet the demands made on it. It is stated that there are many widows and orphans of medical men living in penury and even hunger, and that infirm medical men lack the minor comforts which would ameliorate their lot.

NATIONAL BABY WEEK COUNCIL.—National Baby Week will be celebrated this year from July 1st–7th. The Council urges that special attention should be given to the problem of immunisation, the prevention of maternal mortality, and new developments in maternity and child welfare work. A conference is being organised by the National Association for the Prevention of Infant Mortality on July 4th, 5th, and 6th, and will be followed by an International Child Welfare Congress in Paris on July 8th–12th (see p. 1311). Information about the conference and congress may be had from Miss J. Halford, hon. secretary, National Association for the Prevention of Infant Mortality, 117, Piccadilly, London, W. 1.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.—The annual meeting of this society was held on June 13th at Victory House, Leicester-square, London, W.C., Sir John Rose Bradford presiding. In proposing the adoption of the annual report and balance sheet the chairman said that it was unnecessary to refer in detail to the successful work of the Society during the year as it was fully described in documents which had been circulated. The report contained many matters of considerable interest to the medical profession, while one of the features gratifying to the Committee was the very large number of new members, the largest in any individual year; "but," said the speaker, "when it was considered what a large number of the members of the medical profession did not belong to either of the two medical defence societies the condition of things could not yet be considered satisfactory." The work of the Society had greatly increased in the past few years, for there seemed to be an extraordinary fondness at present on the part of the public for the bringing of actions against medical men. In this connexion the speaker particularly emphasised the necessity of full use being made of X ray examinations as a protection against a large number of litigious claims. Notwithstanding the increased expenditure which the Society had incurred in recent years the total assets were only £1,000 less approximately than previously, while the financial reserves had accumulated to a very satisfactory total. New arrangements had been made with regard to insurance for damages that might be incurred, and these would decrease the expenses of the Society in future years. From the points of view alike of numbers, amount of work done, and the success in performing that work, there could be no question about the Society being in a very flourishing state, while the financial position was also satisfactory. In the course of his address Sir John Rose Bradford expressed the gratitude of the Society to its officials and solicitors for the competent way in which the increased demands upon them had been met. On the motion of Dr. C. M. Fegen the President was re-elected for the ensuing year, the proposer referring to the untiring work of Sir John Rose Bradford on behalf of the Society; all the officers were re-elected, including the auditors, Messrs. Allwork and Co., and the solicitors, Messrs. Le Brasseur and Oakley, were thanked for their conduct of the Society's business. A vote of thanks to the chairman terminated the proceedings.

Dr. Charles Gordon Moore has been appointed Physician in Ordinary to H.R.H. Princess Beatrice in the place of Sir Alfred Rice-Oxley, C.B.E., who has resigned.

STREET ACCIDENTS IN LONDON.—During the months of January, February, and March last in the Metropolitan Police area, the street accidents averaged over 284 a day, and each day three lives were lost. The total of deaths during these three months was 293, as compared with 214 in the corresponding months of last year.

WORLD'S DAIRY CONGRESS.—As we have already announced, the eighth World's Dairy Congress will open at the Central Hall, Westminster, on June 26th. The congress has never before been held in England, and more than 1000 delegates from 47 different countries will attend. Among those who are reading papers are Prof. E. V. McCollum, of Johns Hopkins University, Prof. J. C. Drummond, Dr. H. Corry Mann, Sir John Robertson, and Prof. H. R. Kenwood.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS.—On June 12th the Duke of Connaught, who has been President of the hospital since 1872, formally opened the new block which is to house the surgical and radiological departments. Sir Alexander Butterworth, chairman of the committee of management, said that the policy of the hospital had been to keep the buildings and equipment up to the standard of modern requirements rather than to incur the cost of providing new beds. With this end in view, the Prudential Assurance Company a year ago had generously given new pathological laboratories and a research institute. Now numerous friends and well-wishers of the hospital had subscribed the funds necessary for a new surgical and radiological block. Lack of funds had prevented the committee from embarking years ago upon these much needed improvements. Sir Ernest Birch spoke of the keen interest which was taken by the Royal Family in all voluntary hospital work. The Duke of Connaught pointed out the great changes which had taken place in the treatment of chest diseases since he became President of the hospital; diseases of the heart and lungs were still responsible for approximately half the deaths and much of the ill-health of this country. Within a comparatively short term of years the surgical treatment of pulmonary diseases had attained a position of great importance. The extent to which the use of X rays for diagnostic purposes had grown could be realised from the fact that the radiological department provided 12 years ago had already proved inadequate. The hospital was now furnished with suitable surgical and radiological equipment.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

THURSDAY, June 28th.—2 P.M., UROLOGY. Operations at St. Peter's Hospital. 8.30 P.M. (at 1, Wimpole-street), Prof. Jurasz (Poznan): Paper on Movable Kidney, to be followed by a discussion.

FRIDAY.—11–12 A.M., UROLOGY. Demonstration of special instruments at 1, Wimpole-street. 2 P.M., Operations at St. Thomas's Hospital. 8 for 8.30 P.M., President's Dinner at Verrey's Restaurant.

SATURDAY.—DISEASE IN CHILDREN. Provincial Meeting at the Royal Infirmary, Leicester. 2 P.M. (in the Board Room), *Paper:* Dr. H. Stanley Banks, Senior Medical Officer, Leicester City Isolation Hospital: On the Treatment of Toxic Diphtheria by Large Intravenous Doses of Antitoxin. 2.30 P.M., *Paper:* Mr. C. J. Bond: On the Effect of Certain Radiated Sterols on the Cellular Constituents of the Blood. 3.15 P.M., *Paper:* Dr. G. Brittain Gill, Physician to Braceborough Spa: On Calcium Deficiency and its Treatment. 3.30 P.M. (in Out-patients' Dept.), *Cases:* Dr. Astley Clarke: (1) Resolving Luetic Ascites. (2) Photographs of Apparatus for the Treatment of Acute Anterior Poliomyelitis Involving all Four Limbs. Mr. R. S. Lawson: (1) Raynaud's Disease. (2) and (3) Two Cases of Osteogenesis Imperfecta. (4) Calcaneous Deformity Showing Calcaneous Spring. (5) Anterior Poliomyelitis of Upper Arm, Showing "Shelf" Splint. Dr. J. P. Jamie: Three cases. Dr. A. E. Payne: Radiograms of Kohler's disease. Dr. J. V. C. Braithwaite: (1) and (2) Two Cases of Cœliac Rickets. (3) Lipodystrophia. (4) Hypertelorism. (5) Myositis Ossificans Progressiva. (6) Infantilism with Hypertrichosis. (7) Osteogenesis Imperfecta. 4.30 P.M., Tea in the Hon. Staff Room. 5 P.M., Discussion.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY
49, Leicester-square, W.C.
WEDNESDAY, June 27th.—4.15 P.M., Annual General Meeting, followed by an ordinary meeting. Clinical Cases.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

INSTITUTE of HYGIENE, 28, Portland-place, W.
FRIDAY, June 29th.—3.30 P.M., Dr. C. S. Thomson: A Review of Food Legislation.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, June 25th, to SATURDAY, June 30th.—ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, Great Portland-street, W. Special clinical demonstration in Surgery by Mr. Rocyn-Jones. In Out-patients' Department at 2.30 P.M. No fee.—ROYAL EYE HOSPITAL, St. George's Circus, S.E. Special clinical demonstration in Ophthalmology by Mr. Bickerton at 3 P.M., on Wed. No fee.—WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck-street, W. Special course of lectures and clinical demonstrations upon selected cases for four weeks, 5 P.M. daily.—LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. Practitioners' course in Medicine, Surgery, and the Special Departments, 4.30 to 6 P.M. daily (second week). Further particulars from the Secretary (Mayfair 2236).

NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, June 25th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Grainger Stewart: The Diagnosis of Cerebral Tumours (2).
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Bailey.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Purdon Martin: Chorea.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, June 26th.—3.15 P.M., Dr. B. E. Schlesinger: Rheumatic Heart Disease in Children.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.
WEDNESDAY, June 27th.—3.15 P.M., Demonstration by Dr. T. A. Ross at the Central Hospital for Functional Nervous Disorders, Penshurst, Kent.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.
MONDAY, June 25th.—2.30 to 5 P.M. Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M. Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
On Tuesday, at 2.15 P.M., there will be a demonstration of Medical Cases by Dr. F. G. Crookshank.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
TUESDAY, June 26th.—3.30 P.M. (at the Jessop Hospital), Mr. Chisholm: Gynæcological Cases.
FRIDAY.—3.30 P.M. (at the Royal Hospital), Mr. Yates: Surgical Cases.

Appointments.

KELLETT, FRANK, M.B., B.Ch. Camb., has been appointed Assistant Pathologist to the Laboratories of Pathology and Public Health, Harley-street, W.
MADILL, J. T. H., M.B., Ch.B. Edin., F.R.F.P.S. Glasg., Medical Superintendent of Garlands Mental Hospital, near Carlisle.
PETERKIN, F. G. T., M.B., Ch.B. Aberd., Certifying Surgeon under the Factory and Workshop Acts for the Kirkwall District of the County of Orkney.
SINCLAIR, W. A., M.B., Ch.B. Edin., a Medical Referee under the Workmen's Compensation Act for the Orkney District.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Hon. Jun. Asst. Ophth. S.
Birmingham University.—Asst. Lecturer in Physiology. Also Asst. Lecturer in Biochemistry. Each £300.
Bombay, Cama and Albless Hospitals.—M.O. Rs.800–50–1000.
Bradford City.—Asst. S.M.O. £600.
Brighton, Sussex Throat and Ear Hospital.—Hon. S.
Burton-on-Trent, General Infirmary.—Sen. Res. H.S. £200.
East London Hospital for Children, &c., Shadwell, E.—Surg. to Nose, Throat, and Ear Dept.
Eastern Dispensary, Leman-street, E.—Physician.
Gloucester, Gloucestershire Royal Infirmary.—Res. Surg. O. At rate of £175.
Hackney and Stoke Newington Tuberculosis Dispensary, Kingsland-road, E.—Clin. Tuberculosis Officer. £750.
Hounslow, Heston and Isleworth Urban District Council.—Half-time Asst. M.O. £350.
Hull, City and County of Kingston-upon-Hull, &c.—Asst. M.O.H. £600.
Hull, Royal Infirmary.—Asst. H.S. At rate of £150. Also Cas. H.S. £130.
Inverness District Asylum.—Jun. Asst. M.O. £250.
Kensington, Fulham, and Chelsea General Hospital, 194, Finborough-road, Earl's Court, S.W.—Jun. Res. M.O. At rate of £100.
Kirkwall, Balfour Hospital.—Supt. Also Surgeon and Consultant to County of Orkney. £600.
Leeds Public Dispensary.—Sen. Res. M.O. £200.
Manchester University.—Reader in Materia Medica and Therapeutics. £800.
National Hospital, Queen-square, W.C.—Hon. Surg. Asst.
Newark Hospital and Dispensary.—Res. H.S. At rate of £150.
Newcastle-upon-Tyne, Hospital for Sick Children.—Hon. Phys.
Norwich, Norfolk and Norwich Hospital.—Hon. Phys.
Plumstead and District Hospital, Plumstead High-street, S.E.—Second Asst. M.O. £350.
Preston, Biddulph Grange Orthopædic Hospital.—Jun. H.S. £150.
Preston and County of Lancaster Royal Infirmary.—H.P. £190. Also H.S. £150.
Princess Louise Kensington Hospital for Children, North Kensington, W.—Hon. Anæsthetist.
Rhondda Urban District Council.—Asst. M.O.H., &c. £600.
Royal Army Medical Corps.—Commissions.
Royal Free Hospital, Gray's Inn-road, W.C.—Jun. Clin. Assts.
Royal Naval Medical Service.—Surg. Lieutenants. £453.
St. Mary Abbots Hospital, Marloes-road, W.—Asst. M.O. £250.
Sheffield, Jessop Hospital for Women.—Three Asst. H.S.'s. Each at rate of £100.
Surrey County Council.—Deputy County M.O.H. Also Asst. M.O. £1000 and £600 respectively.
Swansea County Borough.—Asst. Dental S. £450.
University of London.—External Examinerships.
Willesden General Hospital, Harlesden-road, N.W.—Res. H.S. At rate of £100.

The Chief Inspector of Factories announces the following vacancies for Certifying Factory Surgeons: Banchory (Kincardineshire), Stretford (Lancashire), Salford (Lancashire), and Islington (County of London).

Births, Marriages, and Deaths.

BIRTHS.

BEATH.—On June 7th, at Elmwood, University-terrace, Belfast the wife of Dr. R. Maitland Beath, of a daughter.
BUCHANAN.—On June 10th, at a maternity home, Lincoln, the wife of Dr. D. S. Buchanan Navenby, Lincoln, of a daughter.
CURWEN.—On June 17th, at Medina Villas, Hove, the wife of Dr. E. Cecil Curwen, of a daughter.
FORD.—On June 11th, at St. Mary's-street, Stamford, Lincs., the wife of Dr. J. Norman C. Ford, of a son.
LANSDOWN.—On June 15th, 1928, at 106, Woodcote Grove-road, Coulsdon, to Ermyn, wife of R. B. P. Lansdown, M.B.—a son.

MARRIAGES.

ADAMS CLARK—SMITH.—On June 12th, at the Church of St. Bartholomew the Great, Smithfield, London, Dr. Willoughby Adams Clark to Ruth Ashton, eldest daughter of Mr. and Mrs. Edgar Smith, of Stoneygate, Leicester.
BARROWMAN—BURN.—On May 24th, at Penang, Straits Settlements, Dr. Barclay Barrowman, of Klang Selangor, F.M.S., to Marguerite Emily (Peggy), younger daughter of Sir Joseph and Lady Burn, of Rydal Mount, Potters Bar.
CRAIG—BELL.—On June 12th, at Holy Trinity, Brompton, Nicholas S. Craig, M.D., of Cheadle Hulme, to Frances Molly Bell, of Burton-on-Trent.
SHEPPARD—MARSHALL.—On May 12th, at the Cathedral, Rangoon, Arthur Lewin Sheppard, Major, Indian Medical Service, to Edith Trelivíng Marshall, M.B., B.S., daughter of Mr. W. A. Marshall and Mrs. Marshall, of Brighton, Sussex.

DEATHS.

HOWARTH.—On June 15th, at Elvaston, Gerrard's Cross, William James Howarth, C.B.E., M.D., for 15 years medical officer of health for the City of London.
HUNT.—On June 13th, at "Windermere," Sheen-road, Richmond, Surrey, Lewis Gibson Hunt, M.D., J.P.
MACDOUGALL.—On June 12th, 1928, after an operation, John Aymers MacDougall, M.D., F.R.C.S.E., of The Hill, Balerno (formerly of Letterewe-Cannes), in his 84th year.
PRESTWICH.—On June 10th, suddenly, Frank Greenhalgh Prestwich, M.R.C.S., L.R.C.P., of Osgathorpe House, Osgathorpe, Leicestershire, aged 36 years.
WEBB.—On June 9th, at Hillfield-avenue, London, N., Dr. Hugh George Webb, aged 92 years.

N.B.— A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

AN INTERNATIONAL SOCIAL WELFARE FORTNIGHT.

PUBLIC health and social welfare have drawn closer and closer together in the last 50 years, and at the present moment it is a difficult task to define the boundaries of the one or the other. The Latin-speaking countries do not attempt it; they have a comprehensive term "hygiène sociale," covering many activities which in English-speaking countries might be classed in either category. Public health workers will find much to interest them in the programme of the forthcoming International Social Welfare Fortnight, which will open in Paris on July 1st. During its progress four great international congresses will hold their meetings in succession, so that the delegates to each will have an opportunity of meeting those who are working in fields closely allied.

On Sunday, July 1st, there will be a joint inauguration ceremony, to which delegates to all the four congresses are invited, and the President of the French Republic will himself open the proceedings. On July 2nd the International Housing and Town Planning Congress[1] will open at Sorbonne. Among the subjects on the agenda are house-building costs, rural housing, housing of the poor, the mass and density of building in relation to open spaces and traffic facilities, and the difficulties in the way of town and regional planning. The second congress to meet will be the International Congress on Statutory and Voluntary Assistance, organised by a permanent international committee, which has held periodic meetings since 1889. The sessions, as well as those of the two congresses mentioned below, will be held in the new Salle Pleyel. The subjects on the agenda include the substitution of prevention for relief, the relief of foreigners, the "new poor," the aged, and the mentally defective—problems which have been acute during the post-war period of distress through which many European countries have passed. The International Child Welfare Congress will open on July 8th. Its sessions will coincide with those of the International Conference of Social Work, but will be so arranged that delegates may attend both conferences if they choose. Among the subjects on the agenda are maternity homes, breast-feeding, open-air institutions for children, social work for children, and the working of children's courts. Finally, the first International Conference of Social Work will also open on July 8th. The programme includes general organisation of social work, training for social work, methods of social case work, social work and industry, and social work and public health. The Conference over which Dr. Alice Masarykova will preside will hold plenary sessions in the mornings, and in the afternoons will divide up into five sections. Already national committees are working in 26 countries in connexion with this conference, and a large number of delegates are expected, including several hundreds from the United States. Soviet Russia is to be represented by Dr. Semachko, People's Commissar of Health, Moscow. In connexion with these congresses an international exhibition of housing and social progress will be held in the Parc des Expositions at the Porte de Versailles, from June 17th to July 17th.

[1] For particulars apply to Mr. H. Chapman, 29, rue de Sévigné, Paris, 3e.

PERCEPTION OF ACID TASTE.

THE tongue is usually held to be a fairly sensitive judge of acidity, and it is interesting to note that two workers in the Argentine, A. Berlatzky and T. Guevara, have investigated the relation between acid taste and actual hydrion concentration. They found that the limiting concentrations of pH for perception of acid taste were: sulphuric acid, 3·9; nitric, 3·2; citric, 3·9; tartaric, hydrocloric, and lactic, 4·3; acetic, 4·5; phosphoric, 4·7. Mineral acids, by reason of their greater dissociation and consequent greater hydrion concentration in solutions of equal alkali-neutralising power are well known to have a more markedly acid taste; but it might perhaps have been expected that the pH limit of perception of sourness would be the same for all acids. Berlatzky and Guevara suggest that the negative ions (e.g., sulphate and nitrate) have antagonistic action. Sulphate ions have a more depressant action on the nerves than chloride ions, as shown by the fact that concentration limit of the bitter taste of magnesium sulphate is higher than that of magnesium chloride.

This information appears to be new. In International Critical Tables there is a table of the relative sweetness of various substances and some quantitative information on colours, but none on the perception of sourness. This field may be commended to the experimental psychologist.

THE ART OF FLYING.

Captain Norman Macmillan, in a book entitled "The Art of Flying," has touched lightly upon many points of interest, dwelling not too deeply upon any one subject. Those seeking to acquire an insight into the general progress of aviation will enjoy reading it. Paragraphs here and there deal with medical aspects of aviation. Most of the statements made are reasonable and show common sense, although a few border upon the fantastic. The pilot of to-day must possess good physique, true perception (visual acuity and visual judgment), accurate power of performance (neuro-muscular coördination), combined with a temperament which fits him for flying. The first three of these essentials can be estimated by tests employed in the Royal Air Force Medical Service. The standardisation and interpretation of the results of all the special medical tests involved in the routine examination of personnel, whether for combatant service or civil passenger flying, are based upon the attributes of those aviators who, in the estimation of the responsible executive branch of the Service, proved themselves men of stamina, resource, and initiative during the war. Whether or not a candidate possesses the "flying temperament" cannot be judged from the results of any system of experiments or tests in use at the present time the decision remains, in the phraseology of the Service, "a question for the executive."

THE SIMPLEX ASEPTIC CLINICAL THERMOMETER.

Messrs. Coates and Cooper, 41, Great Tower-street, London, E.C., have put on the market a clinical thermometer which is contained in a metal case, 4½ inches long and about ⅜ inch in diameter, the case being retained in the pocket by a clip similar to those used for fountain pens. Within the case an antiseptic fluid surrounds the thermometer when not in clinical use, and means are provided for ascertaining whether the fluid is drying up or not. Without removing the container from the pocket the thermometer is easily withdrawn and replaced, while provision is made against leakage. The complete instrument is as easy to carry as a fountain pen, and the thermometer itself is completely protected and made aseptic.

ANTIMONY AND IPECACUANHA IN MALIGNANT DISEASE.

Prof. R. Minervini, of the University of Naples, who is senior surgeon to the hospitals in that city, is one of those who have a firm belief in the parasitic nature of the blastomata and considerable faith in the possibilities of chemotherapy. He has conceived the idea that parasitic agents, though they may not be found in developed tumours, may at one time have been present, and have promoted or stimulated the cellular proliferation which then continues unchecked, just as an ovum, once fertilised, develops into the blastoderm and embryo. According to his theory, if it is possible by chemical means to arrest the segmentation of the ovum, it should not be impossible to arrest in the same way the cellular proliferation which constitutes malignant tumours. Prof. Minervini has attempted patiently for many years to influence the growth of cancer in the human species and in animals by the action of many metals and metalloids in various forms and combinations. In his hands salts of antimony, especially the potassio-tartrate, have had a beneficial effect, and emetin has also had some influence, especially on deposits in glands when a total extract of ipecacuanha root was used. Prof. Minervini has combined these two agents in a compound under the name antiblastoma, and has used this largely both in hospital and private practice.[1] The remedy is prepared in two forms, a dilute solution for intravenous injection and another preparation for direct or parenchymatous injection, both methods being used simultaneously where possible. Prof. Minervini claims that under this treatment all forms of cancer of whatever organ and whatever stage show considerable retardation in their course; that the most important morbid manifestations such as pain and hæmorrhage are diminished or arrested, that ulcerations show signs of healing, and cachexia disappears. He states that in some cases the tumour was reduced in size and converted into a hard inert mass. Any fresh and bona fide attempt to find some therapeutic agent wherewith to combat cancer deserves attention, but we need not point out that of clinical impressions as to improvement following medicinal measures in cases of malignant disease must be subjected to critical inquiry before they can be accepted.

THE SURGERY OF YESTERDAY AND TO-MORROW.

To the Editor of THE LANCET.

SIR,—Mr. A. S. Blundell Bankart rather understated his case in the letter published in THE LANCET last week. The sentence he quotes from Erichsen's tenth edition, 1895, appears also in the eighth edition, 1884, 11 years earlier.

I am, Sir, yours faithfully,

June 15th, 1928. H. CAMERON KIDD.

COPPER AS A CONSTITUENT OF A HARROGATE WATER.

To the Editor of THE LANCET.

SIR,—In the course of research into the minor constituents of the Old Sulphur and the Chloride of Iron waters of Harrogate, I have definitely isolated a small quantity of copper from the latter source. The discovery is not original, for C. H. Bottomley, in 1880, recorded in an analysis of this water a trace of copper, which has not been confirmed until now. Since it is possible that every constituent, however small in quantity, plays a part in the pharmacology of a medicinal water, I was especially interested in an account in THE LANCET of May 19th from one of your American correspondents of some results obtained by Dr. E. B. Hart and his colleagues, in which anæmic rats were cured when a diet containing ferric chloride and a trace of copper was administered. They suggest that copper may be necessary as a catalyst in the formation of hæmoglobin. Geologically the presence of copper is of importance.

Until recently all the writers on the Harrogate waters have concluded that their origin was in rain water which is believed to percolate to the salt beds, and to reappear at the surface richer in mineral content. Prof. A. Gilligan, who has made a report on the probable relationship between the ore veins in the district and the mineral waters, holds that the waters arise from the depths of the granite and igneous magmatic rock forming the earth's interior. Heat and release of pressure allows a portion to percolate up through the sedimentary rocks, the Harrogate roadstone series, bringing up the saline materials. The finding of copper is evidence in favour of this theory—viz., that the Harrogate waters are "new" and do not depend in any way on rainfall.

I am, Sir, yours faithfully,

A. WOODMANSEY.

Royal Baths Laboratory, Harrogate, May 21st, 1928.

THE CHILD'S DOSSIER.

A MOTHER'S memory of her children's illnesses is a notoriously inaccurate source of information, from the doctor's point of view, and there are many instances in which a physician would be helped by a reliable record of a child's previous health and physical progress. Dr. Ruh and Dr. Garvin have provided a book,[1] attractively printed and bound, which is devised to encourage a mother to keep such a record. It may be questioned whether a busy practitioner, however willing to coöperate, will readily find time to fill in the various forms provided for his use—tests for protein sensitiveness, record of serum administration, laboratory findings, analysis of urine, and so on. The record covers the period from birth to 14 years, and landmarks to be recognised at points in the first six years are tabulated, with the caution that there is great variety of development among normal children. The child here taken as the average is certainly not advanced, since it is not till five years that he is credited with ability to count four objects, and only at six years with a knowledge of the letters of the alphabet. Such a record intelligently and conscientiously kept might be of value where a doctor sees a delicate patient for the first time or in helping him to fill up official forms for school or college, or for life insurance applications, while for the mother it will have a sentimental value of its own. The person who should never be allowed to see it in childhood is, of course, the child whose history it records.

SEX IN PARASITIC WORMS.

THE *Schistosomidæ* are the only group of trematode worms, parasitic in vertebrates, in which the sexes are separate and structurally very different in the adult stage. The development of this differentiation in *Schistosoma japonicum*, the blood fluke of Japan and China, has now been worked out by Mr. A. E. Severinghaus.[1] The eggs are laid by worms in the venules of the human intestinal mucosa and find their way into the bowel. Outside the body, each egg hatches into a free-swimming ciliated miracidium which has to find a specimen of one of the limited number of fresh-water snails which can act as a secondary host. If successful it bores into the tissues of the snail and forms a sporocyst, from the walls of which parthenogenetic eggs are formed; these develop into the cercariæ which leave the snail, burrow through the skin of the mammalian host, if they can find one, and pass to the portal blood system, where they develop into the sexual adults; up to this stage no sexual differentiation is perceptible. Using the hamster as an experimental animal, the author shows that all the cercariæ from a single miracidium are of the same sex—i.e., that sex is determined in the sexually produced egg and remains unaltered by the asexual generation which is interposed in the life history. Any one snail is commonly infected only by a single miracidium; hence, to be successful from the worm's point of view, a human infection must consist of cercariæ from more than one mollusc. The author adds some very interesting details about the influence of one sex on the other. In an animal infected with males only, the worms develop quite normally. But if only females are present, they grow slowly and very imperfectly and the reproductive organs hardly develop at all; if, later on, male cercariæ are introduced, the females rapidly go on to complete normal development and reproduction. One is reminded of the way in which a sexually indifferent oyster may be determined to maleness by the propinquity of a female.

HYPERPROTEINÆMIA.

HYPERPROTEINÆMIA is a very rare condition, and only a few cases have been published in the literature. The list has lately been increased by an account[2] of a case associated with multiple myelomata, in which careful analysis of the plasma proteins was made. The patient was a man of 40, with multiple myelomata of the plasma-cell type, involving the skull, ribs, spine, clavicles, pelvis, upper extremities, and femurs. Radiograms showed rarefaction with punched-out areas, and diagnosis was confirmed by histological examination of a piece of tumour excised from the femur. The urine showed a heavy cloud of albumin, with red and white corpuscles, and casts, while Bence-Jones protein was repeatedly demonstrated. Suspicion that plasma fibrinogen was high was aroused when an attempt was made to take a sample of blood for the estimation of the blood calcium, and it was found almost impossible to get any serum from the blood because the clot failed to retract. Subsequent analysis of the plasma proteins showed that they were increased to 13 per cent., which is twice the normal concentration. This increase was found to be chiefly in the euglobulin and slightly in the fibrinogen. A small amount of Bence-Jones protein was thought to be present in the plasma as well as in the urine. The authors point out that the Bence-Jones protein is chemically and immunologically quite distinct from serum and tissue proteins, and suggest that the increase in the globulin and fibrinogen fraction may be in the nature of a reaction to foreign protein such as is known to occur after the introduction of foreign proteins in animals, as in the production of diphtheria antitoxin in horses. They suggest that this and similar cases of hyperproteinæmia may be explained on the basis of systemic reaction to foreign protein.

BELFAST HOSPITAL FOR SICK CHILDREN.—Work is about to be begun upon the new buildings of this hospital, which is designed for 60 beds, 16 more than in the old buildings. There is no possibility of extending the present hospital or of improving methods of treatment. Although a site of five acres has been given by the Belfast Corporation the cost will be £100,000.

FUNDS FOR CANCER RESEARCH.—Towards the sum of £300,000 which the Council of the Lancashire, Cheshire, and North Wales Cancer Research Campaign hope to raise, £103,078 has so far been subscribed. The Public Health Committee of the Manchester Corporation have decided to recommend the city council to make a grant of £1000 towards the fund. It is hoped that other municipalities will followed Manchester's example.

Chadwick Lectures

ON THE

HISTORY OF EPIDEMIOLOGY

DURING THE LAST HUNDRED YEARS.*

BY SIR WILLIAM HEATON HAMER,
M.D. CAMB., F.R.C.P. LOND.

LECTURE I.

ON a cursory view the history of epidemiology brings to mind Swift's account of the controversies of the Lilliputians. During his first nine months' residence in Lilliput, Gulliver became greatly interested in some of these animated disputes, which were "significant of much"; that of the Tramecksan and Slamecksan, who for 70 moons past had been distinguished from each other by the high and low heels of their shoes, and that of the Little Endians and Big Endians, who disputed as to the proper way of breaking eggs. Gulliver concluded that the differences concerning breaking eggs were merely of a textual character, for, says he, going back to the origin of the whole dispute, the authoritative words are these: "All true believers break their eggs at the convenient end." This is an unexpected volte face, coming as it does from a man who had been apprenticed for four years to a medical practitioner, had studied medicine at a Dutch University, and had had experience as a ship's surgeon; if he had but completed this training by studying epidemiology he would have treated the subject more seriously.

In March, 1918, on the appearance of a new disease, controversy raged in London as to whether food poisoning or encephalitis was in question; on the one hand likenesses and affinities with recognised types of disease, on the other differences, were stressed. The episode emphasised the correctness of Sydenham's view that "the brief life of a single mortal" is not long enough to demonstrate "the fact of certain epidemics succeeding each other regularly and in series forming, as it were, a circle." He, however, when he was confronted with somewhat similar phenomena, in his "epidemic constitution" of 1673–76—the counterpart of our influenza constitution round about 1918—was moved to say: "All that I know is what I know well—namely, that up to the present time it has been exceedingly anomalous and irregular, and that all the diseases which have originated from it have been the same."

This difference of outlook in Sydenham's time as compared with to-day makes us recognise that in epidemiology, as in all branches of scientific inquiry, "general climates of opinion" are encountered. Prof. Whitehead, who borrows this phrase from an author of Sydenham's century, goes on to explain that such "climates" persist about two or three generations—that is to say, for periods of 60 to 100 years. In his "Science and the Modern World" he gives account of four of these climates, those immediately preceding our present climate. They are, first, the "Century of Genius," from Galileo, Kepler, and Shakspeare to Harvey, Milton, Sydenham, and Newton; next comes the eighteenth century, termed by Carlyle (whom Prof. Whitehead quotes) the "Century of Victorious Analysis"—the age of the great French mathematicians and of Kant, Lamarck, Watt, and Volta; then follows an interlude, which Whitehead terms the "Romantic Age," with Wordsworth, Shelley, Keats, Schubert, Carlyle, and Faraday; next in order comes Whitehead's "Age of Professionalism," practically coincident with the nineteenth century, but tending to peter out towards its termination, so that "in its last 20 years the century closed," says Whitehead, with "one of the dullest stages of thought since the time of the First Crusade." (Loc. cit., p. 143.)

It was an interlude of "decadence," "decline," say some. Miss Rose Macaulay prefers to call it a period heralding in advance the modern era, with its revival of the doctrine of relativity. Prof. Whitehead says:—

"The new tinge to modern minds is a vehement and passionate interest in the relation of general principles to irreducible and stubborn facts. All the world over, and at all times, there have been practical men absorbed in irreducible and stubborn facts; all the world over, and at all times, there have been men of philosophical temperament, who have been absorbed in the weaving of general principles. It is this union, of passionate interest in the detailed facts with equal devotion to abstract generalisation, which forms the novelty in our present society. Previously it had appeared sporadically and as if by chance. This balance of mind has now become part of the tradition which infects cultivated thought."

Dr. Brownlee's view may be compared and contrasted with that of Prof. Whitehead.

In 1908 Dr. Brownlee made some very interesting observations on periodicity in the manifestations of genius. He states that "Each period of English energy since the Conquest is associated with increase of population, and if this held also for the period of the Saxon invasion, then up till the present time there have been five waves of expansion, with four intervening periods, in which there was no national response to the intellectual action of the few great men who lived or ruled during these times of depression." These five waves cover 450–550 A.D., 650–800, 1290–1390, then the age from Shakspeare to Milton (Prof. Whitehead's Century of Genius), finally a period which "runs from 1760–1870" covering Prof. Whitehead's next three epochs, and bringing us to the dawn of his new mentality.

Dr. Brownlee said, "The effect of pestilences and famines must clearly be looked for in relation to the physical state of a people. Thus the Black Death, in 1348, little lessened the energies of England; Poictiers was fought in 1356, and the response of the people to the sovereign's policy was that of an energetic nation." On the other hand, "The plague in Athens was the mark of the end of a period. The population had passed their period of increase, and recuperation was necessarily a slow and uncertain process."

Sir Ronald Ross, in his work on malaria, refers to inquiries made on the influence of malaria in promoting the decline of the Greek civilisation, and this suggests that, in these later centuries, the influence upon civilisations, germinal vitality, genius production, and the like, of influenza, is deserving of study. This notion has been especially borne in upon the minds of observers of the great epidemics of the 'nineties and of the years 1915–27.

What special influences, epidemiologically considered, have climates of opinion exhibited?

Dr. Crookshank has stated that "In the last 450 years four periods seem to be indicated; periods marked by different phases of medical thought and observation. The first closes with the era of Willis and Sydenham"—i.e., it covers, roughly, Whitehead's Century of Genius. In it, "wide epidemic prevalences were observed and compared, as a rule, without resolution into component diseases, and symptoms obviously due to forms of meningitis, encephalitis, and myelitis, were described in relation to occurrences that we would now call disease groups."

Thus, in medicine, too, this period was one of genius; it was the age of Harvey and Sydenham, and thus saw both the inauguration of the experimental and the revival of the natural history methods of studying disease. It will be found in the next lecture that there is a notable revival of interest, nowadays, in this period.

The second period of Dr. Crookshank, like that of Prof. Whitehead, covers the eighteenth century; this, the age of "victorious analysis," is described by Crookshank from his standpoint as an age when systems of nosology were based upon symptoms, the symptom groups in question being "usually considered as different elements of special epidemic constitutions." This period saw great growth, of population and material resources, in Europe, with commencement of even more rapid growth in North America; it saw, too, the French Revolution and the inauguration of

* Being two lectures delivered in London under the Chadwick Trust on Feb. 16th and 23rd, 1928. Lecture II. will appear in a coming issue of THE LANCET.

the industrial revolution. Incidentally, it may be noted that the developments in intercommunication and traffic at this time had considerable influence in favouring the spread of epidemic diseases. The century happily witnessed, however, the disappearance of plague from Europe and the inception of considerable improvements in the public health and in social services.

Crookshank's next period (corresponding with Whitehead's "age of professionalism") began in 1800, and in it, appropriately enough, "Persistent efforts were made to distinguish specific diseases by the findings of morbid anatomy." Population and means of communication in Europe and America grew by leaps and bounds. Cholera spread from Asia into Europe and caused much mortality; and influenza was phenomenally rife in the middle third of the century. Influenza again became pandemic in the 'nineties.

Crookshank's fourth period, beginning some 40 years ago, "is characterised by the distinction of many specific diseases by association with specific organisms."

Whitehead presumably had not this characterisation in mind when he affirmed that the commencement of this era was comparable, intellectually speaking, with that of the First Crusade. Whitehead, however, apparently considers that there was an escape from this phase in the early years of the present century. The new century has already had a great influenzal constitution of its own, that of 1915–25.

It was necessary, as a preliminary step, to sketch in broad outline the influences exerted by epidemic disease upon the progress of civilisation before approaching the special subject of the present paper. We have now reached the downward slope of the third of Whitehead's waves, and have to deal with the Age of Professionalism and with the immediate aftermath thereof. Our century begins upon a rising wave of genius and on the flood of the "New Momenta," of which Sir John Simon speaks in his "English Sanitary Institutions"; death-rates are falling, population and industry rapidly growing, but cholera is rife on the Continent.

The Nineteenth Century.

So far as epidemiology is concerned, the atmosphere at the commencement of the nineteenth century might be described in almost as gloomy terms as those Prof. Whitehead applies to the decade at the century's close.

J. F. C. Hecker, in an address, nearly a hundred years ago, to the physicians of Germany, asks "What are we medical men of to-day doing as regards investigating epidemic disease, on a scale commensurate with the extent of our exertions in other departments and worthy of the age in which we live." . . . "Are we," he says, "trying to penetrate with becoming reverence into the sanctuary of cosmical and microcosmical science. . . . Has medical science, as it exists in our days, with all the splendour which surrounds it" (Germany, it must be remembered, had already taken the lead in the patient and indefatigable work of the then commencing "century of professionalism"), "with all the perfection of which it boasts, satisfied this demand? This question we are obliged to answer in the negative." He describes how the doctrine of diseases "nurtured by the storms of centuries" . . . now "speaks clearly to the initiated in the languages of all civilised nations." Yet hitherto it has given an account only of individual diseases, so far as the human mind can discern their nature. In this it has succeeded admirably, and its success becomes every year greater and more extensive. But if we extend our inquiries to the diseases of nations, and of the whole human race, science is mute . . . shows us only an immeasurable and unexplored country which many suppose to be merely a barren desert.

Hecker's appeal in Germany is an indication of the new spirit that was stirring in this country, and one of the first results, here, was the passing of the Public Health Act of 1848, establishing a General Board of Health, which was to continue in operation "for five years and to the end of the then next session of Parliament." The achievements of this Board will always be associated very specially with the memory of three men.

Simon relates how the crucial work of the Board's first six years was carried out, apart from the four successive ex-officio members, by Edwin Chadwick, by an unpaid member, Lord Ashley (who, in 1851, became Earl of Shaftesbury) and (after its first two years of existence) by a medical member, Dr. Southwood Smith. In his account of the struggle between the Board and the "interests" opposed to its policy, Simon says that "most of the force of the attack was aimed personally at Mr. Chadwick," and it was he who bore "the distinction, which has been many a great reformer's crown of laurel, that he was among the best abused men of his time." To the ten years' hard work of Mr. Chadwick prior to 1848, "the nation unquestionably owes," says Simon, that "our statesmen of those times were first awakened to the duty of caring for the Public Health, and that the first of our modern legislative endeavours were made to bring health under the protection of law."

While the humanitarian spirit had then thus at length begun to find practical expression, the thirst for scientific inquiry concerning the laws of hygiene was also aroused. The stirring appeal of Hecker had evoked a fine response in Germany, and Dr. Babington, the translator of Hecker, in 1850, found himself the first President of the newly founded Epidemiological Society of London. Moreover, a certain Dr. Farr was appointed, in 1839, as Compiler of Abstracts in the Registrar-General's Office. "An appointment," says Simon, "which seems to have been due to Mr. Chadwick's early recognition of his merits." Medicine was thus addressing itself to the task of penetrating into the sanctuary of "cosmical as well as of microcosmical" science.

Hecker, in his address to the physicians of Germany, had lamented that epidemiology could not make itself "heard in the noisy tumult of the markets," and he added:—

"Hence it is that the doctrine of epidemics, surrounded by the other flourishing branches of medicine, remains alone unfruitful, we might almost say stunted in its growth. For to the weighty opinions of Hippocrates, to the doctrines of Fracastoro, which contain the experience of the much-tried Middle Ages, and, lastly, to the observations of Sydenham, only trifling and isolated facts have been added."

The frontal attack had, however, been delivered upon "filth diseases," "houses unfit for habitation," and the "free ravages of preventable disease," and one of the early results of this assault was the realisation of the fact that, as Hirsch put it in 1883, there was also needed—

"the founding according to a design, and the building up according to a system, of a discipline which had been the subject of but little labour before, and had still to make good its right to a place among the medical sciences."

He was able, however, to say (at that date)—

"Epidemiology bears a character quite different from that of the science 20 or 30 years ago. It has filled out in proportions and acquired finish to an extraordinary degree."

In illustration of the "finish" referred to, note may be made of an essay by Hecker himself on the "English Sweat," profoundly interesting for the light it throws on our modern influenza.

In the light of the experiences of the 'nineties and of Creighton's reflections following thereon, it was obvious in 1906, that—

"To cling to the individuality of the English sweat and of similar forms of disease contemporaneously prevailing in the several continental countries," was, epidemiologically considered, "an untenable position."

To-day there are the additional experiences of 1915–25 to guide us, and it is possible to appreciate more fully now many of the telling touches in Hecker's description of the English sweats, the interpretation of which was less obvious 20 years ago. Thus we are reminded, in reading about these prevalences, not only of influenza, but also of the widespread prevalences occurring in association with it, described now as "encephalitis lethargica," now as "Japanese encephalomyelitis," or by yet other new—or in some parts of the world quite old and familiar—designations.

Furthermore, when we read Hecker's paragraphs on "Influenzas" (p. 218), his note (p. 222) on the sweating character of the influenza of 1580, and his remark (p. 223) that "he must at least point out the relation which the influenzas bear to the greater epidemics"; when (p. 200) we find him connecting "the petechial fever of Southern Europe with the sweating sickness of the North," and read his comments on the epidemics of 1517, especially noting

(p. 227) his "feeling fully justified in classifying those of Holland and Germany with the influenzas," and when, finally, he speaks of their "being a forerunner of the English pestilence which was simultaneously prepared by the altered condition of the atmosphere and broke out a few months later," we must admit that he approached prodigiously close to identifying the English sweats with influenza.

A further illustration of the "finish" alluded to by Hecker is afforded by studies made in tropical countries of dengue. The maps prepared to illustrate the Milroy Lectures of 1906, show that widespread prevalences of influenza and dengue have throughout the epidemiological history tended to be interchangeable. Thus the West Indian Islands suffered from "influenza" in the world-wide prevalence of 1789–90, but in 1826–28 and in 1849–50, when influenza was again pandemic, "dengue" held the field in these islands; in subsequent years the West Indies reverted to use of the term influenza. Similar phenomena can be traced in British India and in the East Indies.

But while epidemiological field work, on the continent, in this country, in America, and in the tropics was thus slowly establishing an ordered system of records, a new development, potent no doubt ultimately for good, but attended temporarily by much counterbalancing retarding influence was now to be inaugurated. It is very interesting to recall the fact that, as long ago as 1881 in a letter to THE LANCET, Sir William Collins clearly pointed out that, while much had been achieved, there was already apparent a slackening in the rate of progress; he clearly saw, in fact, nearly half a century ago, the little cloud rising out of the sea no bigger than a man's hand, and prophesied the approaching storm. He developed his thesis in an Abernethian Society paper in 1884, entitled "Specificity and Evolution in Disease," in which he said:—

> "There can be no doubt that the tendency of pathology during the present century, thanks chiefly to the enormously increased means at our disposal to facilitate diagnosis, and fostered by the teaching of Bretonneau and Laennec, has been to specificise disease; and, while the recognition of the doctrine of specificity has done much to push on our knowledge by insistence on detail, and the estimation of minute differences, it is quite possible that this tendency may have served its end and surpassed its utility. That such is really the case we are frequently and forcibly reminded by disorders which come constantly before us, the so-called anomalous cases, where disease does not breed true, or where hybrid symptoms are developed, cases which do violence to our theories and defy our classification."

Sir William Collins added—

> "the solution of this difficulty lies in a more thorough recognition of the doctrine of evolution as applied to disease, as ruling and directing specificity."

Dr. J. T. C. Nash and other followers of Sir William Collins have made further contribution to this study of evolution and disease. Meanwhile, the rain descended and the floods came and beat upon the epidemiological house.

Pasteur's researches focused attention upon germs, and Koch's special technique dates from the late 'seventies and the early 'eighties. There were quite frequent announcements by those, who were working at bacteriology in the 'eighties, regarding the compliance of successive newly described organisms with Koch's postulates. The old epidemiology, like the silk stockings of Sir Jno. Cutler, was darned with worsted until so little of the original silk remained that no one could be sure that any of it was really left. The situation, it is true, became less strained when de Schweinitz, in 1903, demonstrated that hog-cholera was due to a "filter passer," and not, as had been previously supposed, to the hog-cholera bacillus. Already, in 1894, Gottstein had suggested that pathogenic germs might be merely playing the part of "associated organisms" ("jeweiligen Begleiter") in established conditions of disease, and a few years later O. Liebreich put forward the conception of "Nosoparasites"—i.e., of pathogenic germs which are not parasites proper, but parasites of diseases—that is, "accompanying" or "secondary" organisms. Moreover, in 1908, Hottinger declared that Koch's four conditions should be enlarged "by the addition of a requirement that the infectious character be exhibited by inoculated animals," and speaking more generally, he adds, the condition should be insisted upon "that the artificially produced disease must fulfil the requirements of epidemiology."

In preparing, for the History of Medicine Section of the International Congress of Medicine of 1913, a paper on "The History of Epidemiological Research during the last Seventy Years"—i.e., from the year 1843, when Pasteur came of age and Robert Koch was born—the influence of the great epidemics of the 'thirties and 'forties, of Chadwick's strenuous labours, of the aspirations of German scholars, and of the Epidemiological Society of London (founded in 1850), were all envisaged, and reference was made to Hirsch's dictum of 1881, that so great a change of outlook in epidemiology had come about that what was now needed was "an entirely new treatment of the subject."

It was also appreciated that bacteriology itself was beginning, shortly after the end of the nineteenth century, to recognise that a halt must be called for realignment. It was agreed that bacteriologists had then "outgrown Koch's postulates as Koch himself outgrew them," and that account must be taken of the results of 50 years' patient examination by epidemiologists "of the influence of environment, of conditions of filth, overcrowding, dampness, unwholesome and infected water, milk and food"; all this, taken together with increasing knowledge of protozoology, filter passers, enzymes, and the recent demonstration of mutability of bacilli, made it clear that still more attention must be devoted to the systematic development of a discipline as conceived and exploited by Hirsch. It was accordingly urged that further progress in knowledge of epidemic diseases was only to be gained by bringing about a "unity of opposites." As Prof. Caird says, "The thinker who has fully seen into the correlativity of given opposites has reached a new attitude of thought in regard to them. They have become to him inseparable elements of a higher unity, which is now seen to be organic or vital."

Fifteen years ago, then, it was urged that more energy must be devoted to cultivation of Hirsch's discipline with the object of further filling out its proportions, and giving it more complete finish. But it was not at that time fully realised that a line of advance to be followed was already clearly marked out. The great influenzas of 1915 and onwards brought the rude awakening, stimulating epidemiological inquiry in much the same way as similar epidemics had done in times gone by. Now, however, the path had been blazed through the forest by a great epidemiologist, who already in 1894 had focused attention upon the need for bringing into a higher unity the supposedly opposed teachings of Sydenham concerning epidemic constitutions, and of Pasteur and Koch regarding the germ theory of disease.

Chas. Creighton, who had rendered epidemiologists in these islands the signal service of translating for them Hirsch's great work on "Historical and Geographical Pathology," published in 1891, the first volume, and, in 1894, the second and final volume, of his "History of Epidemics in Britain." I will not here attempt to give an appreciation of those epoch-making volumes; the most remarkable characteristic of the work is, that a pathologist by training, in an age when pathology with the added prestige contributed by the new bacteriology was steadily acquiring growing importance, calmly set to work to fill out the proportions and give more complete finish to the old epidemiology. But this new teaching must form the theme of my second lecture.

PETERBOROUGH NEW HOSPITAL.—Field-Marshal Sir William Robertson has formally opened the Peterborough and District Memorial New Hospital. The building and its site have cost nearly £95,000.

ST. MARY'S HOSPITAL, PADDINGTON. — The Governors have purchased, at a cost of £65,000, a large block of property in Praed-street, South Wharf-road, Cambridge-place, and Union-place, upon which it is intended to build a new medical school, an inoculation department, and a new home for nurses. The site, which is self-contained, is larger than that occupied by the hospital and the existing medical school, and the space liberated by the closing of the present nurses' home will be used for the accommodation of paying patients.

THE MENTAL ASPECT OF CHRONIC EPIDEMIC ENCEPHALITIS.

BY P. K. MCCOWAN, M.D. EDIN., M.R.C.P. LOND., D.P.M.,
DEPUTY MEDICAL SUPERINTENDENT, WEST PARK MENTAL HOSPITAL, EPSOM;
AND
L. C. COOK, M.R.C.S. ENG., D.P.M.,
ASSISTANT MEDICAL OFFICER TO THE HOSPITAL.

THE problems of the mental disorders associated with chronic epidemic encephalitis have been overshadowed, in the enormous literature, by the neurological and moral aspects. We have had the opportunity of investigating many uncertified cases and of observing daily, for three or four years, over 120 certified cases at West Park Mental Hospital, and 24 cases in the Manor Institution for mental defectives. In this paper an attempt is made to describe some of the mental characteristics noted, to discuss some of the difficulties in diagnosis, and to construct some sort of classification for the multifarious symptoms. No classification appears yet to have been formulated, at any rate in the English language, and although the writers are only too conscious of the difficulties of such a task and of the short-comings of their venture, they hope that it may lead to a clearer conception of the mental pictures and to more successful attempts from other pens. It must first of all be clearly recognised that the groupings arranged are by no means mutually exclusive and are, in fact, rarely found singly; but this applies equally to all classifications of mental disorders. Again, it is not at all uncommon for the mental picture to change from one type to another in the same individual.

Classification.

(*a*) Bradyphrenic.
(*b*) Depressed: (1) reactive; (2) agitated; (3) hypochrondriacal; (4) psychasthenic.
(*c*) Paranoid: (1) systematised delusions; (2) unsystematised delusions.
(*d*) Apache: (1) delinquent; (2) restless.

The Encephalitic Temperament.

The encephalitic temperament is marked by a definitely simple and childish outlook and a regression in emotional values, well seen in the morbid craving for attention exhibited by nearly all sufferers. The patient and his illness "must occupy the centre of the stage."[1] The doctor, entering the ward, is greeted by every patient; those who can walk may follow in a body, each vieing to attract first attention to himself, whilst the most helpless of Parkinsonians attempts as well as he can to bring the doctor to his side. Unlike the epileptic, who usually has some complaint to make, the encephalitic may have nothing in particular to say but merely desires recognition.

While one of us was taking several encephalitics for a car ride, one of them, who was in the dicky, suddenly tapped the driver on the shoulder in the midst of dense traffic, and asked a question, which was unintelligible owing to the noise and the patient's indistinct speech. He persisted with his question until the driver had to pull up the car by the side of the road in case something serious was the matter. The question then turned out to be: "What make of car is this?" Only with an encephalitic would such an incident be possible.

Again unlike the epileptic, he will be definitely, though often quite transiently, affected by the attitude of the visitor towards him. Like a child, he is hypersensitive, and overvalues the trivial greetings of those attending him, being put out by incidents which would pass almost unnoticed by the average normal adult. Many mental defectives show somewhat similar characteristics, but the encephalitic tends to show keen insight into his own disease; he displays greater interest in his symptoms and a more detailed knowledge of his treatment than does the normally intelligent sufferer from some other serious disease. One small girl of 11, who had very definite intellectual deterioration as shown by successive Binet tests, could give a detailed account of her history and symptoms, could recite at length the opinions of various doctors on her primary attack, and volunteered the names of several drugs with which she had been treated. It is probably this abnormal brightness about their own illness that has led many physicians to aver that there is no mental deterioration in many of these patients, even in some who have been certified. It doubtless also accounts for the statement that encephalitic Parkinsonism is usually associated with euphoria. What is really present is an emotional facility and, as nothing gives the encephalitic more pleasure than to describe his symptoms to an interested audience, he does on such occasions exhibit a childish elation. This, however, is only a passing phase, and close observation shows some degree of mental degeneration in nearly every case. Although the main changes lie in the emotional sphere, there is an accompanying loss of ordered judgment, an inability to view things in their proper proportion; in fact, a return in greater or lesser degree to the outlook of childhood. Another noticeable characteristic in the majority of these cases is abnormal suggestibility.

Seven female patients were given, in addition to their morning injections of hyoscine, a small dose of hyoscine by the mouth at 1 P.M. After some time this was replaced by flavoured water. A few noticed the slight change in taste and were told that it was a different brand of hyoscine, probably stronger. All said they were as well if not better than before. Some days later the oral dose was altogether withdrawn. With one exception they all complained of feeling very much worse and begged to be put back on the "hyoscine." All these patients suffered from various degrees of Parkinsonism, the majority showing little intellectual defect. It is not intended to suggest that the effect of hyoscine in Parkinsonism is entirely a functional one; on the contrary, the beneficial effect of this drug upon the tremor, rigidity, and general feeling-tone of these cases has been repeatedly proved.

This fundamental temperament is seldom found alone, and is often overshadowed by the more striking features of bradyphenia, apache behaviour, &c.

Bradyphrenic Type.

The main body of Parkinsonians, in addition to the characteristic temperament, display a retardation of cerebration which is usually, but by no means always, proportionate to their individual physical retardation (bradykinesia). This symptom, which appears to be correlated with an unpleasant sense of effort in initiating thought or movement, brings poverty of ideation as a natural corollary in its train. The psychic and psychomotor processes which are essential to thought and voluntary movement should be capable of considerable mobility and rapidity of action in initiating, changing, or stopping such thought or movement. Something interfering with normal induction in these reflexes (Sherrington) would explain the mental viscosity which occurs in bradyphrenia and for which no localised lesion could account. A function of the whole nervous system is affected, for bradyphrenia and bradykinesia must be regarded as the same phenomenon acting at different levels of the nervous system. It has been shown by Delmas-Marsalet[2] that the stiffness or hypertonia of Parkinsonism and the slowness of movement in bradykinesia are independent phenomena. This is borne out by clinical experience and accounts for many phenomena which at first sight seem paradoxical. In it may lie the explanation of the different results obtained from the exhibition of hyoscine in Parkinsonism. This drug acts by abolishing any extrapyramidal hypertonicity present. For Parkinsonians who have little or no such hypertonicity hyoscine proves practically useless.

All grades of bradyphrenia are found, from mild retardation to marked lethargy. The latter sit or lie with eyes closed, apparently asleep; they are only aroused with difficulty, and every attention has to be given them. This somnolence is, of course,

quite different from the drowsiness of the acute stages. It is important to differentiate the bradyphrenic who has merely lost the power of emotional expression from the stuporose patient who has lost the power of feeling emotion.

Depressed Type.

Depression is by no means an uncommon symptom, and we have subdivided it into reactive, agitated, hypochondriacal, and psychasthenic groups.

1. *Reactive depression* depends upon the peculiar sensitiveness of the patient to the gravity of his disease and is mainly evident in the early stages of Parkinsonism. The patient feels his increasing disabilities becoming an intolerable burden, which added to his regressive temperamental changes, is only too likely to lead to thoughts of suicide. As in other reactive depressions, the apparent cause is doubtless only precipitating, the latent cause being some flaw in the mental make-up. In these cases, however, the flaw need not be a serious one, as the precipitating cause is so severe. It is a difficult and depressing task to realise philosophically that one has suddenly ceased to be the man one was, that all one's dearest ambitions and hopes must be forever foregone and replaced by the picture of a life of chronic invalidism. Real adaptation, however, calls for this philosophical outlook, and any other form of reaction must be regarded as regressive. We may regard this class as having made a compromise, preventing complete regression by obsessive preoccupation with their situation, and so long as the regressive tendency is thus satisfied, the mood is essentially one of anxiety or depression. Detention in a hospital where constant attention, freedom from responsibility, and the presence of others similarly afflicted are to be found is usually instrumental in bringing about an adjustment. Instead of this improvement, a state of mild stupor of variable duration may follow, but only two such cases have been encountered by the writers.

2. *Agitated Depression.*—Occasionally a condition of agitation and confusion with motor and psychical restlessness, obsessional delusions, and hallucinations has been noted.

CASE 1.—Male, aged 33, displays a striking picture of agitation, confusion, and emotional dilapidation. He is subject to delusions of substitution and reference, and is actively hallucinated. He sees strange creatures and people coming out of holes in the walls or ground. He bursts into tears with the utmost facility, bemoaning his lot in a confused and emotional manner. There is a history of a characteristic acute attack of encephalitis, and this diagnosis is supported by the neurological signs now present. Before admission he was depressed and suicidal.

3. *Hypochrondriacal depression* is less rare and is not to be confused with the morbid interest taken by so many patients in their symptoms. These patients are true hypochrondriacs and have a genuine belief in their many and varying imaginary symptoms. Owing to their mental and physical disabilities many encephalitics are precluded from dominating their environment in the usual way through their personality and normal activities, and have regressed to the stage of exploiting physical disease as a means of attracting attention, a somewhat similar mechanism to that seen in other hypochrondriacs with their dulled "health conscience."

4. *Psychasthenic Depression.*—States of anxiety, obsessional impulses and doubts, and feelings of inadequacy and infirmity, characteristic of Janet's conception of psychasthenia, are not uncommon.

CASE 2.—A single woman of 35, suffered from a febrile attack in April, 1924. She was very drowsy and was in bed for a fortnight. Later on inversion of sleep rhythm was prominent. She has never fully recovered from this attack, but has felt nervy ever since and has suffered from "pressure on the top of the head." She now has a distressing polydipsia which causes extreme agitation and depression and has led to two attempts at suicide. Polyuria sometimes amounts to over 300 c.cm. daily. Regular injections of 0·5 c.cm. pituitary extract have a slight but transient effect, and it appears that the water-drinking is an obsession. The patient is intelligent and has never lost insight, but is anxious about herself, worries continually, and is altogether lacking in confidence. Physically there is a suggestion of stiffness about the features, and her skin is rather greasy. Her right arm is often held fixed and adducted, and cog-wheel movements can be elicited at times. There is an occasional tremor of her right hand, which is sufficient to prevent the performance of fine movements.

Paranoid Type.

This is the smallest of the four groups, but the fact that 10 per cent. of our patients belong to it shows that the type is by no means uncommon, at least among certified cases. These patients are preeminently suitable for a mental hospital, and doubtless practically all of them are sent there sooner or later. Its recognition is important, as many of the symptoms —e.g., hallucinations and definite delusions—are considered by other observers to be extremely rare, and in the absence of signs of Parkinsonism it is extremely difficult to distinguish this type from ordinary cases of paraphrenia (systematised delusional insanity) and dementia præcox. In fact, cases crop up, with indefinite histories of acute attacks of encephalitis and with no neurological signs, in which it is almost impossible to arrive at a definite diagnosis. The relative infrequency of delusions of persecution in encephalitic psychoses is really rather surprising in view of the peculiar temperament of these patients. Their constant preoccupation with their illness and symptoms should make a fertile ground for such delusions, especially of the type sometimes described as hypochrondriacal paranoia.

We have subdivided the group into two classes, according to whether the delusions are systematised or not.

1. *Systematised Delusions.*—The commonest symptoms are ideas of reference, pseudo-reminiscences, and hallucinations of all senses, but especially of hearing; delusions, chiefly persecutory but sometimes pleasantly erotic, usually autopsychic but also somatopsychic. The content of the delusions is often palpably dependent on the physical symptoms. The usual paranoid interpretation of events is seen and the affective state is congruous with the delusions. Some cases are absolutely indistinguishable from the usual paraphrenia, but certain distinguishing features may be noted in a majority. The chief of these is a definite periodicity in the activity of the delusional symptoms, which drop into the background for longer or shorter periods, during which some patients have quite a fair insight into their condition, and others can be temporarily convinced that their beliefs are delusional. Another characteristic is that with the progress of bradyphrenia all paranoid symptoms may gradually disappear.

CASE 3.—Male, a moderate Parkinsonian of 35, is extremely suspicious and suffers from various delusions of reference and persecution. At times he thinks that other patients are staring at him and pointing him out because they know he masturbates. He hears references to himself and feels that he is an object of contempt. He complains of patients putting something on his clothes at night, which gives them a fish-like smell, and he also suspects the staff of trying to poison him. He possesses very fair intelligence and at times has partial insight into his condition.

CASE 4.—Male, a moderate Parkinsonian of 20, shows a similarly suspicious outlook and is subject to delusions of persecution. He is aurally hallucinated and complains of people talking about a love affair of his. These symptoms sometimes disappear for months, but when they return the contents of his delusions are always the same.

CASE 5.—Male, an advanced Parkinsonian of 45, for two years presented a picture of ordinary paraphrenia with ideas of reference, auditory hallucinations, and delusions of persecution referable to his environment. He gradually developed an increasing bradyphrenia, ceased to exhibit these symptoms, and is now in a state of advanced lethargy.

CASE 6.—Female, a marked Parkinsonian of 21, whose psychosis is superadded to some degree of feeblemindedness, is superficially a typical dull, retarded bradyphrenic. She is, however, actively hallucinated by "Jimmy," who is constantly calling to her. She wanders through the ward and gardens searching for him and eagerly goes up to strange visitors or workmen, hoping to find her friend. Any

reference to her "Jimmy" will provoke an immediate smile and there is no doubt that she gains much pleasure from her innocent phantasy.

2. *Non-systematised Delusions.*—Much the same series of symptoms is found in this class—viz., ideas of reference, hallucinations, &c. The delusions, however, are definitely unsystematised, often varying much from day to day, and, when inactive, are discussed by the patient with schizophrenic indifference. The content of the delusions points to a much greater degree of regression than in the former group and may be frankly sexual. Emotional dilapidation is evidenced by impulsive and apparently motiveless outbursts of violence, and by incongruity between the affective state and the conduct of the patient. In short, the mental picture is indistinguishable from that found in many schizophrenics.

CASE 7.—Female, a moderate Parkinsonian aged 27, is a confirmed masturbator, subject to impulsive outbursts of screaming and smashing for which she can offer no adequate reason. She is actively hallucinated, hearing the voices of her mother and child. She is extremely irrational, with various fleeting delusions based on her hallucinatory experiences. When questioned about her symptoms, she adopts an indifferent schizophrenic attitude towards them and fails to regard them as in any way abnormal.

CASE 8.—Female, a slight Parkinsonian of 26, has outbursts of window-smashing, very similar to those of Case 7. They are usually preceded by a phase of depression, in which she hears the nurses saying she has a "sarcastic face." She is also hallucinated by the voice of one of the medical officers, which continually reproaches her. She, too, adopts an indifferent schizophrenic attitude towards her hallucinations.

CASE 9.—Male, a marked Parkinsonian of 18, is convinced that he is suffering from worms which have entered his body per urethram. He states that he can feel them moving about inside him and maintains that recovery can be brought about only by their removal. The presumption that these somatopsychic delusions were initiated by proprioceptive or enteroceptive sensations is in no way incompatible with the fact that the patient's present attitude towards them is essentially that of a sufferer from dementia præcox. This schizophrenic indifference is so great as to mask successfully the customary interest of the encephalitic in his illness.

The Apache Type.

The term apache has been used almost universally in the description of cases of chronic epidemic encephalitis whose chief characteristics are delinquency and bad conduct, and therefore the apache syndrome is here meant to include all behaviour irregularities, from mischievousness to serious crime. It is seldom found in patients who have passed adolescence at the time of their primary attack. On the other hand, apache symptoms may continue, as far as we know, indefinitely. The condition appears to depend partly on a heightened irritability and diminished power of control and partly on a lack of reasoned judgment and self-criticism. This mechanism may well be that of "regression due to removal or suppression of the epicritic control over the protopathic instinctive tendencies."[3] In any case, the result is a more or less complete disintegration of those psychological sentiments which contribute to the social and moral senses. Children of irreproachable family, hitherto of exemplary behaviour and character, may in a very short period become guilty of every delinquency from mere naughtiness to cruelty and murder, and from mild bad habits to gross indecencies. We have only met one case of sexual perversity in an adult encephalitic. This is a male Parkinsonian of the bradyphrenic type, aged 40 years, who was considered well enough to be discharged to the care of his friends but who had to be returned to hospital as he started exposing himself indecently in front of his children.

Motor restlessness is a striking feature in these patients and may be responsible for the numerous cases of "wandering," as well as for their pugnacity. Tics and nervous habits are common, varying from simple movements and grimaces to complicated performances. Peculiar anomalies of gait are seen, such as flexing one knee at every step, constantly changing step, revolving round, &c. Several patients run up to speak to the doctor and then throw themselves on to their backs with their legs half in the air; one boy actually turns a complete somersault. That this phenomenon is not due to imitation is proved by the fact that such cases are found both at West Park and at the Manor Institution, and that their antics have been noted soon after admission and before they had had any opportunity of seeing other encephalitics.

It is convenient to divide the apache group into those whose most prominent symptom is delinquency and those who are chiefly distinguished by restless, troublesome behaviour. The former may provide a picture of "moral imbecility," which is seldom seen outside encephalitis. The latter show a more aimless activity in which restlessness, interference with others, irritability, and quarrelsomeness are prominent. To this type Hall gives the name of the "difficult child," and there is no doubt that many become quite unmanageable at home and yet show no really vicious or criminal tendencies. With the majority, however, it is merely a question of which form of activity predominates, and, although the division is convenient for clinical purposes, there is probably little psychological difference in these cases between aimless mischief and seeing what can be found in somebody else's pockets. Prominent in some apache cases, with or without Parkinsonism, are periodic outbursts of acute excitement which may last for several days. During these periods the patient may be noisy, destructive, impulsively violent, and sometimes hallucinated.

Differential Diagnosis.

Bradyphrenic.—There is usually no difficulty in diagnosing the bradyphrenic class, as Parkinsonism is invariably present. It is sometimes stated that the catatonic stupor of dementia præcox closely resembles encephalitic Parkinsonism. This is certainly true of the outward appearance of the two diseases, but in practice there is little difficulty because of the profound difference in mentality. The catatonic is indifferent, sometimes entirely inaccessible; his voice may be affected, and his ideas are almost certainly irrational. The characteristic indistinct monotonous slur of the encephalitic Parkinsonian is conspicuously absent. The gait may show similarities but, if advantage be taken of the automatic obedience of so many catatonic patients, a few sharp commands will frequently alter gait and posture in a striking manner. The main criteria, however, lie in the constant absence of inaccessibility and indifference in the typical emotional reactions of the encephalitic. A few hypodermic injections of hyoscine may be a valuable aid to diagnosis, as they frequently lead to immediate improvement in the Parkinsonian but have no effect on the catatonic.

A very real difficulty arises in diagnosing early cases of catatonic dementia præcox from the somnolent phase often found in acute epidemic encephalitis, and the prominent part that epidemic encephalitis now plays in the lay and medical press, combined with the knowledge that many cases of this disease have passed unrecognised, has created a tendency to give epidemic encephalitis the benefit of the diagnostic doubt in difficult cases. As a matter of fact there are fundamental differences in the mental pictures. The catatonic patient has periods of stupor of greater or lesser degree alternating with periods of excitement, and when these latter occur at night, as they commonly do, the patient superficially resembles the encephalitic with inversion of sleep rhythm. If the encephalitic is roused, however, he is accessible; his answers are rational and he will not express any delusional ideas. The catatonic, on the other hand, may exhibit automatic obedience, remain mute even if roused, or show definite evidence of being hallucinated, and will usually unfold a delusional thought-content. Even in his periods of excitement the encephalitic rarely voices the

bizarre delusions so common in the catatonic, and he certainly does not do so in his quiet moments. The following case illustrates this difficulty :—

CASE 10.—A single girl of 20 was admitted to West Park Mental Hospital with the following history. She had been vacant, dreamy, and strange in manner for about two months. For two or three weeks she had been wont to sit in one position, gazing out of the window instead of doing her work as a housemaid. At night she was restless and talkative, and slept badly. She was at length sent home and seen by a doctor, who sent her to a general hospital where she was kept under observation for a day and a night. She was restless and troublesome during the night and was next day sent to an infirmary with the diagnosis of epidemic encephalitis. On admission here the following day no neurological signs of epidemic encephalitis were present. She showed a gait simulating the Parkinsonian and an affected type of speech. She was rather irrational and showed incipient dementia. She was definitely apathetic, and when roused her manner was indifferent and uninterested. The diagnosis of dementia præcox has been abundantly confirmed.

A recent text-book states that Parkinsonians are usually apathetic, but it is essential to recognise the difference between bradyphrenia and the true stupor reaction. The encephalitic may be supremely dull but is not indifferent. True stupor is rarely seen in chronic epidemic encephalitis, but when it does occur it may completely efface the more usual encephalitic temperament. Again, as the disease progresses, an emotional dementia like that of other organic brain diseases often supervenes. By this time, however, the physical signs are so prominent that no difficulty in diagnosis should arise.

Depressed.—The commonest type of encephalitic depression is reactive and largely dependent upon the disabilities of Parkinsonism. As a rule there should be no difficulty in diagnosing it from the depressed phase of the manic-depressive psychoses. Alternations with elation are common in the latter, and there is frequently a past history of similar attacks or of family mental disorder. If the patient has insight, then, unlike the Parkinsonian, he is unaware of the cause of his depression ; while, if he has not, he usually puts it down to imaginary sins. We have seen no cases of manic-depressive insanity in the chronic stages of epidemic encephalitis. More interesting, however, is the diagnosis in those cases who show no Parkinsonism, but whose mental changes include loss of concentration, easy fatigability, sense of effort and inadequacy, fits of depression and tears, anxieties, and obsessions. Psychasthenia and anxiety hysteria are frequently simulated, and in the absence of Parkinsonism the diagnosis must depend on the past history and on isolated signs. Case 2 presents some of these symptoms, and the following case may be of some diagnostic interest :—

CASE 11.—A girl of 16 was admitted to West Park Mental Hospital six months ago, since when she has behaved well, has been a good and willing worker, and appears to be quite trustworthy. She is inclined, however, to be solitary and rather sullen, and is sometimes found weeping bitterly for no apparent reason. Her outlook is abnormally childish and simple for her age. She takes violent fancies to certain nurses, and is inordinately upset by the slightest sign of displeasure on their part. Physically there are no signs of Parkinsonian, but nystagmoid movements and a convergence defect, together with a rather definite history of diplopia, make up a fairly characteristic ocular syndrome. She is said to have had "sleepy sickness" in 1919, and since then has been through a phase of wandering at night, using filthy language, and indulging in indecent behaviour. She has also attempted to commit suicide.

A mistaken diagnosis of neurasthenia or psychasthenia can often only be avoided in early cases by thorough investigation into the history and by careful examination of the central nervous system. Just as an apparent case of neurasthenia coming on between the ages of 30 and 50 should bring to mind the possibility of general paresis, so a similar syndrome in younger patients should lead to thoughts of epidemic encephalitis.

Paranoid.—The paranoidal types of epidemic encephalitis cannot be distinguished with any certainty from other paranoid psychoses in the absence of definite physical signs or of a conclusive history of an acute attack.

Apache.—The apache type must be distinguished from mental deficiency per se, from dementia præcox, and from mania. From mental deficiency there is no difficulty when the symptoms appear after a definite primary attack. In fact, apache symptoms appearing in a child or young adult of hitherto normal behaviour and normal intelligence are strongly suggestive of epidemic encephalitis, even in the absence of other evidence. There are, however, difficult cases, which have a legal as well as a medical interest, as when encephalitis attacks those who come from an insane or defective stock or who have been feeble-minded from an early age. In such people, whose self-control is already poor and whose judgment is subnormal, the pathway of regression to completely uncontrolled and vicious actions is most easily traversed. There may be only a vague history or perhaps none at all, and here it is doubtful if one can make a diagnosis with any great degree of certainty. Nevertheless, those who come into contact with a large number of mental defectives of all types, as at the Manor Institution, Epsom, hold the opinion that there is a definite difference. The encephalitics are the most troublesome and pugnacious children in the ward. Their delinquencies are more wanton, more bizarre, more constant, and more intractable ; and yet they are usually the most popular patients with the nursing staff. They are seldom cowards and, although they will bully smaller children heartlessly, they will also hold their own with older and stronger patients. When taken to task, their comments are often ingenious and show some sense of humour. These characteristics are due in part to the increased motor and psychic activity, which is a more constant feature in the encephalitic apache than in the mental defective.

The presence of major or minor epileptiform fits by no means excludes the diagnosis of epidemic encephalitis.[4] Quite a few of our patients are subject to fits indistinguishable from those seen in true epilepsy. Petit mal attacks are also seen, and it may be that some of the very transient oculo-gyric crises are of this nature. One case under our care has frequent attacks in which his eyes momentarily turn upwards and to the left, while a vacant glassy expression comes over his face. Atypical, especially mesencephalic (decerebrate) convulsions are more suggestive of encephalitis than of epilepsy. A history of epileptic fits going back to early childhood is, of course, against the diagnosis of encephalitis. In doubtful cases, with indefinite histories and physical signs, the general behaviour and temperament should give a good idea of the true cause.

Another important factor in the differentiation of the apache encephalitic from the troublesome defective lies in the ratio of intelligence disorder to behaviour disorder. The encephalitic is almost invariably intellectually superior to his conduct. When marked apache behaviour appears in cases of pure mental deficiency, it is usually associated with a condition of idiocy or low-grade imbecility, and the intelligence-behaviour ratio is approximately equal.

The outbursts of temper in some apache types are not unlike the impulsive outbursts of the catatonic dementia præcox in their sudden onset and severity ; impulsive smashing, for instance, is seen in both conditions. The key to diagnosis lies in the conduct between attacks. The præcox is irrational, detached from the outer world, and usually hallucinated. The apache is emotionally facile but shows none of the præcox symptoms.

The suggestion that apachism is really a form of mania [5] cannot be supported. The superficial similarity between the two conditions is less noteworthy than the fundamental differences. The cardinal symptoms of mania are flight of ideas, elation, and increased motor activity. The apache admittedly shows an excess of motor restlessness, and some patients are for ever on the move, peering into everything and

getting into continual mischief, fidgeting with their hands and feet even when seated. This restlessness, however, is quite different from the "press of activity" of mania. Again, the lack of concentration and easy distractibility of the apache differ greatly from the flight of ideas of the maniac. The attention of the latter, passing rapidly from one subject to another, embraces an enormous amount of ideational material, while that of the apache tends to hover over a relatively narrow field. Five minutes' conversation with a restless apache will see him return to one subject, often even one sentence, half a dozen times. In short, the apache shows some degree of ideational poverty which is in sharp contrast with the evident fertility of ideation seen in mania. In the former type a definite "goal idea," childish though it may be, is undoubtedly present, whereas mania is associated with a garrulity in which any sort of "goal idea" is conspicuously absent. Of true elation the average apache shows little evidence. The childish euphoria which he exhibits while carrying out his various peccadilloes or discussing them and his other symptoms depends on his childish reactions and emotional facility, and is very different from the sustained sense of well-being of the manic patient. Lastly, if apachism were merely a form of mania, one would surely be justified in expecting to find an occasional case which showed the cardinal symptoms of mania in an unmistakable manner over a reasonable period, but the writers have met no such case in a chronic encephalitic, either with or without apachism.

We should like to thank Dr. Norcliffe Roberts, superintendent of West Park Mental Hospital, and Dr. E. S. Littlejohn, superintendent of the Manor Institution, for allowing us to publish the cases. We should also like to express our gratitude to Dr. E. Mapother for many helpful suggestions and criticisms.

A NOTE ON THE EFFECT OF ACETYLARSAN IN EARLY SYPHILIS,

WITH SOME REMARKS ON ITS TOXICITY.

BY V. E. LLOYD, *M.C.*, M.B., B.S. LOND.,
DIRECTOR OF THE VENEREAL DISEASES DEPARTMENT, GUY'S HOSPITAL.

BEFORE the introduction of salvarsan Ehrlich had carried out many investigations on the therapeutic effect of various organic arsenical compounds. One of the earliest preparations was a member of the group of pentavalent arsenical compounds known as "atoxyl." This compound, as shown later by Fourneau [1] was originally prepared by Bechamp [2] in 1863 and was the sodium salt of *p*-aminophenylarsinic acid. Before long severe toxic effects, notably sudden amblyopia, were reported and finally led to its disuse. Later two more members of this group were introduced into the therapeutics of syphilis; arsacetin, the sodium salt of acetyl-*p*-aminophenylarsinic acid and hectine, the sodium salt of benzo-sulpho-*p*-aminophenylarsinic acid. These two preparations, although much less toxic than atoxyl, were by no means free from undesirable sequelæ; arsenical nephritis frequently followed the use of arsacetin. On the introduction of the group of trivalent organic arsenical compounds, of which salvarsan is the outstanding member, and later of its modification neosalvarsan, the interest in pentavalent arsenicals underwent a temporary eclipse. Further interest in them was aroused by the introduction, in 1919, by Jacobs and Heidelberger,[6] of tryparsamide, the sodium salt of N-phenylglycineamido-*p*-arsonic acid. Its effect in the treatment of neuro-syphilis has been reported upon favourably by many observers, who have also drawn attention to the occasional occurrence of amblyopia as one of the more severe toxic effects. In this respect it is similar to atoxyl. In 1922 Levaditi [3] and Navarro-Martin renewed interest in the pentavalent organic arsenical compounds by their report upon the therapeutic action, in experimental syphilis, of stovarsol. This compound, acetyl-oxyaminophenylarsinic acid, originally prepared by Ehrlich, Benda, and Bertheim [4] in 1908, was reinvestigated by Fourneau [5] in 1922. The addition of the acetyl radicle renders this compound more stable and far less toxic than its forerunner atoxyl, to which it is closely allied. The therapeutic effect of the oral administration in human syphilis has been studied by Fournier, Quenot, and Schwartz,[7] who reported that its action was inferior to that of the arsenobenzenes.

Recently another member of the pentavalent series of organic arsenical compounds has been in use in France where it is now manufactured under the name of acetylarsan.* This preparation, which is closely allied to and a derivative of stovarsol, is stated to be *p*-oxy-acetylamino-phenylarsinate of diethylamine. The therapeutic effect in the various stages of syphilis has been reported upon favourably by Laurent [8] Lacapère,[9] and Tribet.[10] Acetylarsan is supplied immediately available for therapeutic use, in an aqueous solution containing 23·6 per cent. of the compound. The solution, which is neutral in reaction, colourless, and clear, contains 5 cg. of arsenic per c.cm.; each c.cm. is equivalent to 0·25 g. of novarsenobillon (N.A.B.) in arsenic content.

It may be administered intravenously, intramuscularly, or subcutaneously; the latter is most generally utilised. Subcutaneous injection, under the skin of the buttock, was the method selected in the cases under consideration; complaints of local reaction following injection were exceptional.

Dosage: The maximum dose tolerated in rabbits is 40 cg. per kg. In man the ratio of administration is 2 cg. per kg.; from 1 to 5 c.cm. of the aqueous solution may be administered, the general plan of the treatment being an injection of 3 c.cm. twice weekly or 5 c.cm. once a week. These injections may be repeated until a total of 48 c.cm. (11 g.) is attained at the end of eight weeks. For the treatment of women slightly smaller quantities are given or the intervals are lengthened; the total amount in a course being 8 to 9 g. For the treatment of congenital syphilis in infants a less concentrated solution, which contains 9·4 per cent. of the compound, is provided by the manufacturers, and will be found more convenient than the concentrated solution designed for adults. The normal dose for infants is 1·5 cg. per kg. of body-weight; for an infant of 6 lb. weight an injection of 0·15 c.cm. of "infantile acetylarsan" is given; this is increased at four-day intervals until 0·45 c.cm. is reached; this amount is not exceeded in any further injection.

This preparation is eliminated rapidly, chiefly in the urine.

In the series of cases under consideration treatment with acetylarsan was carried out in 26 cases of early syphilis, of whom 17 were in the primary stage, and 9 in the secondary stage; of these cases 9 were women and 17 were men. Certain observations were made upon the spirillicidal, serological, and clinical effects of the subcutaneous injection of acetylarsan in these cases.

Effect of Acetylarsan on S. pallida.†

Observations have been made upon the period of survival after treatment of *S. pallida* in the secretion of the primary lesion in 11 of these cases. The results in each case indicate that no spirochætes survive in the superficial layers of the primary lesion after a period of 24 hours following the injection of acetylarsan. In certain cases the spirochætes were killed within 6 to 12 hours. Table I. indicates the results of the subcutaneous injection of 3 c.cm. (0·7 g.) of acetylarsan on the spirochætes in the secretion of the primary lesion. *S. pallida* were present in abundance in all

* Manufactured by the Laboratoire des Produits Usines du Rhone, 21, rue Jean Goujon, Paris.

† I am indebted to the sole agents, Messrs. Wilcox, Jozeau and Co., 15, Great St. Andrew-street, W.C. 2, for the free supply of a large proportion of the acetylarsan used in the treatment of these cases.

cases at the time of injection, except that few were noted in Case No. 2761.

TABLE I.

Case No.	Age of chancre.	Result of subsequent examination for *S. pallida*.
2669	One day.	None detected 8 or 30 hours later.
2780	Three days.	None detected 24 hours later.
2741	Seven days.	None detected 24 hours later.
2761	Eight weeks.	None detected 24 hours later.
3072	Four days.	A few distorted spirochætes seen 9 hours later.
3001	One week.	A few seen 6½ hours later, but none 12 hours later.
1797	Five weeks.	None detected 24 hours later (*a*).
1770	One week.	None detected 14 hours later.
3598	Four days.	A few seen 17 hours later, but none 24 hours later.
2993	Three weeks.	None detected 10½ hours later.
3122	One week.	None detected 24 hours later.

(*a*) Case No. 1797 received only 2 c.cm. (0·47 g.) of acetylarsan.

Effect of Treatment with Acetylarsan on the Wassermann Reaction.

The effect, as reflected by the result of subsequent Wassermann reactions, of a short course of treatment in all cases which attended long enough, is reported below. Fourteen out of the total of 26 cases are here considered. Of the remaining 12 seven ceased attending before completing the first course of treatment; in one case, on account of unavoidable irregularity of attendance, treatment with N.A.B. was substituted. Two cases suffered from toxic effects necessitating the cessation of treatment; two further cases are too recent to include in this section.

(*a*) *Sero-negative Cases.*—Three cases of sero-negative primary syphilis in this series were treated with acetylarsan; the result of W.R. after treatment of varying intensity is shown below.

CASE 2741.—Male aged 24. Attended on May 9th, 1927, with a primary chancre in which spirochætes were numerous; W.R. negative. He was treated from May 9th to July 18th with 17 injections of acetylarsan, a total of 12 g. W.R. negative on June 17th and again negative on August 5th, one month after end of course.

CASE 3001.—Male aged 33. Attended on July 28th, 1927, with two primary chancres of seven days' duration, containing many spirochætes. W.R. negative. From July 28th to Sept. 16th he received 11 injections of acetylarsan, a total of 7·8 g. W.R. negative on Sept. 8th, six weeks after the commencement of treatment.

CASE 2669. Male aged 58. Attended on April 23rd, 1927, with a primary chancre of one day's duration, in which numerous spirochætes were found. W.R. negative. After receiving only three injections of acetylarsan, a total of 2·25 g., he ceased attending for six weeks. On his return on June 14th W.R. negative. Further treatment with acetylarsan was given from June 14th to July 26th, during which period 13 injections of 3 c.cm. were given, a total of 9·2 g. On August 2nd W.R. still negative.

Into this group fall two additional cases of primary syphilis which, although the W.R. was not done at the time of first attendance, were most probably sero-negative; after a course of treatment with acetylarsan W.R was negative in both cases.

CASE 3072.—Male. Attended on August 12th with a primary chancre of one week's duration; *S. pallida* present. From August 12th to Oct. 3rd he received 10 injections of acetylarsan, totalling 7·08 g. W.R. negative on Sept. 15th, Oct. 31st, and Dec. 19th.

CASE 3068.—Male. Attended on August 11th with a chancre of one week's duration in which *Sp. pallida* were present. Injections of acetylarsan were given from August 11th to Oct. 3rd, a total of 11 g. On Nov. 10th W.R. was negative. From Nov. 17th to Dec. 23rd a second course of ten injections was given; W.R. again negative on Dec. 23rd.

(*b*) *Sero-positive Cases.*—In seven of the nine sero-positive cases a negative W.R. resulted after the initial course of treatment; in one of these signs of intolerance to acetylarsan made it necessary to continue the treatment with bismuth. The remaining two cases showed some serological improvement, but their reactions did not become negative. The histories of these cases are reported briefly.

(*a*) *Cases Resulting in a Negative W.R.*

CASE 2761.—Male. This case had a primary chancre with inguinal adenitis; there were no secondary manifestations; the W.R. was weakly positive. From June 2nd to August 6th eight injections of 3 c.cm. of acetylarsan were given; on August 17th W.R. was negative.

CASE 2779.—Male. Gave a history of a penile sore four months ago; presented specific ulceration of the fauces, alopecia, and general adenitis. W.R. positive. From May 26th to July 16th a course of 16 injections of acetylarsan, 3 c.cm., was administered, a total of 11 g. On August 17th W.R. was incompletely negative. A second course of 12 injections of 3 c.cm. of acetylarsan, totalling 8·4 g., was given from August 25th to Oct. 6th. W.R. negative on Oct. 3rd and on Nov. 7th.

CASE 3056.—Male, aged 30, with a primary chancre and a secondary eruption of 14 days' duration; W.R. strongly positive. From August 9th to Sept. 20th he received 13 injections of 3 c.cm. acetylarsan (9·2 g.). On Oct. 19th W.R. was negative.

CASE 1797.—Female. A case of primary and secondary syphilis; positive W.R. From May 16th to July 20th she was given 13 injections of acetylarsan, totalling 8·5 g. On July 27th and August 22nd W.R. was weakly positive. From August 26th to Dec. 6th 2 c.cm. of acetylarsan were administered on 16 occasions, a total of 7·52 g. On Dec. 20th W.R. was negative.

CASE 1798.—Female aged 26. A case of secondary syphilis with cutaneous eruptions and condylomata; W.R. strongly positive. From May 16th to June 7th she received 13 injections of acetylarsan (8·5 g.). On July 13th W.R. still strongly positive. From August 12th to Nov. 15th she was given 15 injections of 2 c.cm. of acetylarsan (9·0 g.). On Nov. 22nd W.R. negative.

CASE 1914.—Female aged 34. A case of secondary syphilis with a generalised eruption of a few days' duration; W.R. strongly positive. From July 23rd to August 29th seven injections of 3 c.cm. of acetylarsan were given. On account of irregular attendance only two further injections were given, one on Sept. 20th and one on Oct. 22nd. W.R. negative on Jan. 9th. The total amount of acetylarsan administered was 6·3 g.

In the following case acetylarsan was tolerated for a few injections only and treatment by bismuth was substituted; the combination of these two preparations had a favourable effect upon the result of the W.R., which became negative.

CASE 1840.—Female aged 51. A case of syphilis in the secondary stage with a strongly positive W.R. From June 8th to June 23rd she received four injections of acetylarsan (2·8 g.); toxic effects prevented the further use of this preparation, which was replaced by intramuscular injections of bismuth. From June 29th to Oct. 14th she was given grs. 48 of bismostab. W.R. negative on Oct. 26th and without further treatment was again negative on Dec. 21st.

(*b*) *Cases showing some Serological Improvement.*

CASE 1844.—Female. A case of secondary syphilis of a few weeks' duration with condylomata of the vulva and anus. The W.R. was strongly positive. She was treated from July 11th to August 22nd with 13 injections of acetylarsan (total 7·55 g.). On Sept. 19th W.R. was weakly positive; she did not attend again.

CASE 2834.—Male, aged 47. Had a primary chancre of unknown duration; W.R. strongly positive. From July 28th to Sept. 9th he received 16 injections of acetylarsan (total 11·2 g.). An erythema of arsenical origin prevented further treatment. On Dec. 17th W.R. was incompletely negative.

Effect of Acetylarsan on Clinical Lesions.

The rate of healing of the primary lesions following the administration of acetylarsan, as seen in Table II., compares favourably with that of salvarsan and its substitutes.

TABLE II.

Case No.	Age of primary lesion.	Time elapsing before healing.	No. of injections.	Total.
3001	7 days.	6 days.	2	6 c.cm.
2669	1 day.	4 ,,	1	3 ,,
1770	7 days.	5 ,,	1	3 ,,
1841	4 weeks.	20 ,,	2	6 ,,
1797	5 days.	7–10 ,,	2	6 ,,

On the secondary eruptions this preparation acts rapidly; in one case a roseolar eruption disappeared in six days after one injection of acetylarsan;

condylomata in two cases disappeared in 14 days, during which time four injections were given.

Toxicity.

The first member of the pentavalent group of organic arsenical compounds to be used in the therapeutics of syphilis was atoxyl. Following the use of this preparation toxic effects, among which optic atrophy was prominent, were frequent and severe. It has since been suggested by Fourneau,[1] who reinvestigated the chemical structure of atoxyl, that the majority of toxic effects previously attributed to this compound were due to impurities, chiefly sodium arsenite. However, it must be noted that ocular toxic effects may also follow the treatment of neurosyphilis with tryparsamide, another member of this series.

The experimental work of Voegtlin and Thompson [11] has demonstrated the rapid elimination of arsenic in the urine and fæces of rats, following the administration of compounds of the pentavalent group; in the majority of the compounds used by these two observers, the secretion of arsenic in the first 24 hours was between 80 and 90 per cent. They have also shown that in some of the pentavalent compounds the toxicity for rats is inversely proportional to the rate of elimination; no such correlation was found in the case of salvarsan or neosalvarsan. Voegtlin, Dyer, and Miller [12] have shown that the toxicity and parasiticidal action of the rapidly excreted pentavalent compounds is increased by ligation of the ureters and also of the bile-ducts in rats. They consider that the retention in the tissues is requisite for effective therapeutic value.

No detailed figures are available of the elimination rate of arsenic during the first 24 hours following the administration of acetylarsan. Laurent [8] reports that following the subcutaneous injection of oxyacetylaminophenylarsinate of sodium (sodium stovarsol) a pentavalent arsenical closely allied to acetylarsan, a considerable amount of arsenic was detected in the urine five hours later, and that elimination was complete at the end of 72 hours. Chattelier, Mahoux, and Valdigué [13] report that arsenic can be detected in the urine ten minutes after the administration of acetylarsan, and that elimination is practically complete within 36 hours.

In view of these observations one would expect acetylarsan, which is a member of this pentavalent group, to be less toxic than salvarsan or its substitutes in equal quantities. On account of the rapid elimination of the pentavalent compounds, however, it is found that the effective doses are higher than those of the arsenobenzenes, and the maximum quantity tolerated is also higher. The maximum dose of 3 c.cm. (1·18 g.) of acetylarsan is equivalent in arsenic content to 1·15 g. of N.A.B. Acetylarsan is usually given bi-weekly in doses of 3 c.cm., a weekly total of 6 c.cm., equivalent in arsenic content to 1·5 g. of N.A.B. In spite of the rapid elimination of acetylarsan it is difficult to avoid the suspicion that there may be more accumulation of arsenic in the tissues with acetylarsan than with N.A.B., and that toxic effects, especially of the late variety, may be more frequent. Comparison of the total quantity injected in a course of acetylarsan with that of a course of N.A.B. also has a bearing on the expectation of cumulative toxic effects. The maximum course of acetylarsan used in this series consisted of 16 injections of 3 c.cm. each, forming a total of 48 c.cm.; each c.cm. contains 0·236 g. of acetylarsan, the total arsenic content being 2·02 g., an amount which is administered in eight weeks. A course of N.A.B. of moderate intensity consists of a total of 5 g. administered over a period of 12 weeks and corresponds to 1 g. of arsenic. Thus the quantity of arsenic administered in this course of acetylarsan is double the amount of arsenic in an average course of N.A.B. and is given in a shorter period. The excretion of arsenic in the pentavalent group is almost totally via the kidneys (80–85 per cent.), whereas in the arsenobenzenes a considerable proportion is excreted in the fæces, in the case of salvarsan 82 per cent. and N.A.B. 33 per cent.

This would lead us to expect more frequent toxic effects on the renal tissue during treatment by a member of the pentavalent group; such effects were frequently met with in the use of atoxyl and arsacetin. In all 88 cases were treated for a variable period with acetylarsan; the cases in this series, which includes the 26 cases of early syphilis already discussed, are classified in Table III.

TABLE III.

Stage of syphilis.	Total.	Male.	Female.
Primary	17	14	3
Secondary	9	3	6
Tertiary	19	1	18
Latent	24	3	21
Congenital	19	—	19
Total	88	21	67

In these 88 patients, for whom the total number of injections was 854, toxic effects were met with in 14 cases—i.e., in 15·9 per cent. of cases and after 1·6 per cent. of injections. Table IV. indicates the incidence and severity of the toxic effects encountered, together with the sex distribution.

TABLE IV.

Cases.	Injections.	Reactions of slight degree.		
		With no interruption of treatment.	Temporary cessation of treatment.	Complete cessation of treatment.
Men, 21 ..	272	2	0	1
Women, 49	402	1	1	9
Children, 18	180	0	0	0
Total, 88 ..	854	3	1	10

All the toxic effects were slight. In three cases treatment was not interrupted and no further ill-effect occurred. In nine cases, all in women, treatment by acetylarsan was entirely stopped, not on account of the intensity of reactions, but in deference to the wishes of the patients.

Toleration.

No vasomotor reactions of the type known as "nitritoid crises" were met with, nor were there any examples of delayed arsenical poisoning giving rise to late jaundice or exfoliative dermatitis. It should be noted that no case has been under treatment for a longer period than nine months, and that it is still possible for either of these two complications to occur. In a series of 37 cases treated by Chatellier, Mahoux, and Valdigué [13] there were no cases of jaundice or exfoliative dermatitis; Poli-Garnier [14] treated 21 cases and Laurent [8] 66 cases without meeting either of these two complications. Lacapère [9] comments on the infrequency of reactions and has met with none of a serious character. Acetylarsan was administered to one pregnant patient in this series; it was well tolerated and no ill-effects were noted or complained of. Poli-Garnier [14] treated 21 cases during pregnancy with excellent results to the subsequent child; no toxic effects in the mother were reported.

This compound was extremely well borne by the children in the series; none were less than 12 months old and none were suffering from early or severe congenital syphilis. The age-distribution was as follows: age 1–3 years, 5 cases; age 3–5 years, 3 cases; age 5–10 years, 8 cases; age 10–13 years, 2 cases. Laurent [8] has reported favourably on the toleration of acetylarsan in four cases of congenital syphilis under the age of 1 month.

Reaction.

The reactions were diverse.

(1) The most frequent phenomenon was headache a few hours following the injection, associated with general malaise and in some cases a slight rise in

temperature. This occurred in four cases, in each case following the third or fourth injection.

(2) Vomiting a few hours after an injection occurred in four cases; in three it followed the second or third injection but in one case was not experienced until the sixth and was repeated after the ninth injection. Nausea and vertigo without vomiting were complained of in two additional cases.

(3) A complaint of feeling feverish and of malaise, both of transient duration, was made in two cases.

(4) A toxic erythematous eruption was seen in two cases; in one, a month after the end of the first course of 16 injections, a generalised erythema appeared which disappeared within seven days. A second case developed an erythema of the arms and neck on the day following the fourth injection; the eruption disappeared in four days.

(5) Albuminuria, which was anticipated, was experienced in one case only, a girl aged 20, in whom a trace of albumin was present three days after the eighth injection, but had disappeared 24 hours later. Albumin reappeared after the eleventh and thirteenth injections, but was small in amount and transient in duration on both occasions. Later a second course of 16 injections was tolerated without any return of albuminuria. In a case of congenital syphilis, in whom albuminuria had followed the previous administration of N.A.B., the toleration of acetylarsan was perfect.

(6) Jaundice of very slight degree and transient duration appeared in one case after the third injection; this had completely disappeared in 12 days.

(7) A Herxheimer reaction occurred once, in a case which presented a fading secondary syphilide; a few hours after the first injection the eruption again became bright in colour and subsequently faded rapidly. This case later suffered from recurring albuminuria and has already been referred to.

No toxic effects upon the nerve tissue were met with. Sudden amblyopia from effects on the optic nerve, as experienced with atoxyl and tryparsamide, was not seen in any case of this series, among which were three cases of tabes dorsalis, and one of syphilitic pachymeningitis.

Conclusions.

(1) The effect of acetylarsan on *S. pallida*, as estimated by their disappearance from the secretion of the primary lesions, is equal to that of the arsenobenzenes.

(2) The early serological effect, as far as can be judged in these few cases, compares favourably with that of the arsenobenzenes.

(3) Acetylarsan is more frequently followed by minor toxic effects than the arsenobenzenes; in this series no toxic effects of a serious nature were noted.

I wish to express my gratitude for the support received from all the medical officers of the Venereal Diseases Department, Guy's Hospital, during the observations of these cases.

ABSORPTION OF BLOOD FROM THE PERITONEAL CAVITY.

By HOWARD FLOREY, M.B. Adel., Ph.D. Camb.,*
HUDDERSFIELD LECTURER IN SPECIAL PATHOLOGY IN THE UNIVERSITY OF CAMBRIDGE;
AND
L. J. WITTS, M.D. Manch., M.R.C.P. Lond.,
JOHN LUCAS WALKER STUDENT IN THE UNIVERSITY.

The intraperitoneal administration of whole blood has been applied in the treatment of infants where blood transfusions are indicated. Blood cells introduced into the peritoneal cavity are absorbed intact via the diaphragmatic lymphatics into the blood vascular system, so that an intraperitoneal injection is equivalent to a very slow intravenous transfusion. The diaphragmatic lymphatics and the thoracic duct are practically the sole channel for the absorption of particulate substances from the peritoneum. The basement membrane, which elsewhere forms a continuous sheet under the serous surface of the peritoneum, breaks up into a fenestrated membrane on the abdominal surface of the diaphragm, and particles are able to pass through the fenestrations to reach the lymphatics.[1] A factor of the utmost importance for their absorption is the intra-abdominal pressure; the greater this is the more rapidly are particles forced into the lymphatic system. It has already been shown that the absorption of a graphite ink may be very greatly accelerated by compression of the abdomen; the ink particles, which pass between the peritoneal cells lining the diaphragm, issue from the thoracic duct within three minutes of intraperitoneal injection.[2] It seemed probable, therefore, that massage might promote a quicker absorption of intraperitoneal blood and, if this were so, that it might form a useful adjunct to this procedure, especially in weak infants with atonic belly walls. To test its effect a series of experiments has been performed on dogs. The results of one experiment have been summarised in tabular form, and a diagram has been drawn of the rate of flow and the concentration of red cells in lymph from the thoracic duct of another.

Some five hours before the anæsthetic the dogs were given a meal containing fat, so that at the time of operation the thoracic duct would be filled with fatty lymph and easily visible. Chloralose, 0·1 g. per kg., was given intravenously after preliminary ether anæsthesia; one animal received morphia subcutaneously and paraldehyde by stomach-tube. In successful experiments the duct was located in the neighbourhood of the left external jugular and subclavian veins. In all cases a cannula was inserted directly into the duct. In many studies of thoracic duct lymph the cannula has been inserted into the external jugular vein near its junction with the subclavian, and the internal jugular, subclavian, and innominate veins have been tied off. This is often an easier operation than directly introducing a cannula into the duct, but it is difficult to be certain that all the small entering veins have been ligated. Lymph from the thoracic duct is of a creamy-white or serous appearance, depending on the amount of fat it contains. It clots readily and apparently more rapidly when blood is being absorbed from the peritoneal cavity. It contains normally only a very small number of red cells, and flows with a well-marked respiratory variation, welling up into the cannula with each expiration. During apnœa a small quantity of lymph is expelled at each cardiac pulsation. Increased respiratory movement accelerates the flow. Pressure with the hand on the abdomen causes a temporary increase. In the first three dogs the flow of lymph decreased soon after the experiment was begun. These dogs had received an intravenous injection of chloralose dissolved in about 50 to 100 c.cm. of normal saline, which might account for the large initial flow. In dog 4, which was anæsthetised with morphia subcutaneously and paraldehyde by stomach-tube, the flow was quite even, and about 130 c.cm. of lymph were collected during an experiment lasting nearly seven hours. All the lymph was collected and measured to estimate the flow, and samples were taken at regular intervals for blood

* With a grant from the Medical Research Council.

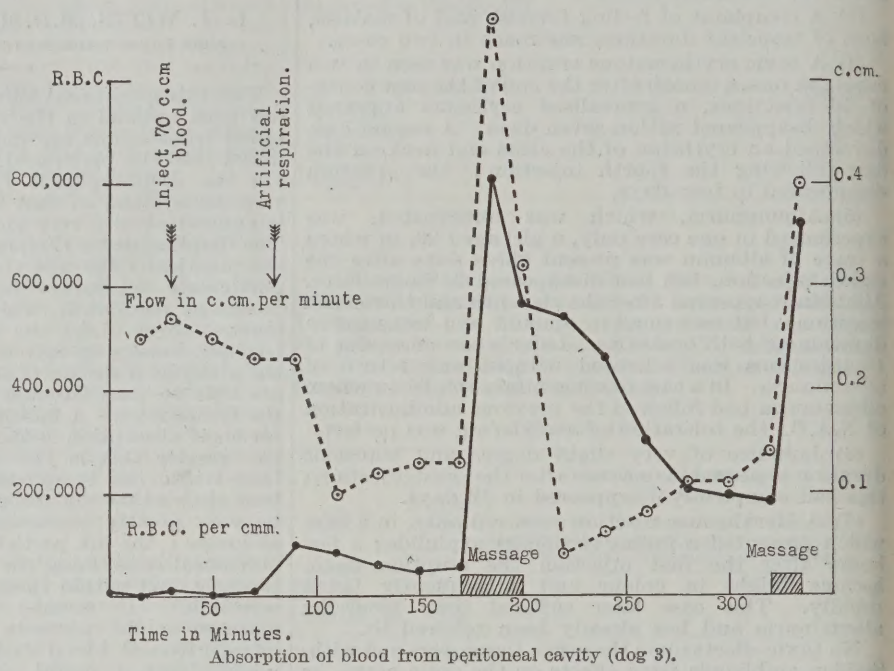
[2] H. Florey: Brit. Jour. Exp. Path., 1927, viii., 479.

counting. When a steady flow was established, 70 to 100 c.cm. of defibrinated dog's blood were injected into the peritoneal cavity. Preliminary experiments had shown that blood corpuscles from a different species were rapidly hæmolysed. For example, into each of two rabbits 20 c.cm. of hen's blood were injected intraperitoneally. Samples of blood were taken from the ear veins for several hours after the injection, but no nucleated red cells were seen. 100 c.cm. of sheep's blood were injected intraperitoneally into a dog; the red cell count in the lymph from the thoracic duct never exceeded 18,000 cells per c.mm., though the lymph became a bright transparent red. The colour suggested a count of at least half a million, and it was obvious that the majority of the red cells must have been hæmolysed. For this reason dog's blood was used in the experiments now reported. When the rate of absorption of red cells had reached a steady level, the abdomen was vigorously massaged for 30 minutes. The experiment was continued long enough for the recovery period to be studied.

No constant change in the rate of flow occurs after injection of blood into the peritoneal cavity. Red cells appear in the lymph 20–40 minutes after the injection and the colour of the lymph changes to pink or red. The time elapsing before a steady level is reached and the ultimate concentration of the red cells in the lymph depend apparently on the rate and depth of respiration. In dog 3 (weight 5 kg.) with shallow artificial respiration the flow was stabilised for one hour at 0·12 to 0·13 c.cm. per minute and 50,000 to 64,000 red cells per c.mm. In dog 4 (14 kg.), which developed rapid respiration after gr. $\frac{3}{4}$ of morphia, the flow varied over 80 minutes from 0·21 to 0·25 c.cm. per minute and the concentration of cells from 340,000 to 317,000 per c.mm. In dog 3 stabilisation of the rate and concentration began 100 minutes after the injection of the blood, in dog 4 160 minutes after injection. In dog 1 stabilisation had apparently just been reached at 0·38 c.cm. per minute and 155,000 cells per c.mm., but in these earlier experiments insufficient time was allowed. Similar levels were reached after recovery from the effect of massage.



Absorption of blood from peritoneal cavity (dog 3).

Result of Experiment on Dog 4.

B.I.I. = 80 c.cm. blood injected intraperitoneally.

A.M. = Abdominal massage.

Blood injected: 6,860,000 R.B.C. per c.mm. Blood in peritoneal cavity at conclusion of exp.: 9,000,000 R.B.C. per c.mm. Blood in diaphragmatic lymphatics at conclusion of exp.: 4,390,000 R.B.C. per c.mm.

An examination of the data from the experiments shows that absorption of blood from the peritoneal cavity is a relatively slow process. The rate of absorption would appear to be a resultant of the vigour of respiration and the tone of the abdominal muscles. We have worked with strong healthy dogs. Maximum absorption occurred in dog 4, which was a muscular animal weighing 14 kilos, exhibiting hyperpnœa for the greater part of the experiment. After the intraperitoneal injection of 80 c.cm. of blood containing 6,860,000 cells per c.mm., about 100 c.cm. of lymph, which had on an average less than 300,000 cells per c.mm., passed out of the thoracic duct—i.e., only one-sixteenth of the total number of corpuscles injected was absorbed in six hours. Thus, even with vigorous respiration and strong abdominal muscles, the absorption of the blood is a slow process. This must very greatly limit the value of intraperitoneal blood transfusion.

Massage has a considerable effect on the number of red cells and the rate of flow of the lymph. The flow may be increased fivefold and the cells reach from 500,000 to 800,000 per c.mm. Some part of this increased flow is due to the emptying of the receptaculum chyli and the lymphatics of the abdominal viscera by pressure. These initial sources are soon exhausted and the enhanced rate of flow is maintained by the increased intra-abdominal pressure. This promotes an increased absorption from the peritoneal cavity of both fluid and corpuscles as shown respectively by the rates of flow and the rise in the number of cells in the lymph. It must be emphasised that the massage was more forceful than could be applied to human patients, the abdomen being compressed firmly from 15 to 20 times a minute. After massage there is a temporary decrease in the flow, due to the filling of the lymph channels, while the concentration of the cells returns slowly to the pre-massage level.

The blood used for injection contained about 7,000,000 red cells per c.mm. Fluid obtained by puncture of the diaphragmatic lymphatics at the end of the experiments contained about 5,000,000 red cells per c.mm. The figures illustrate the extreme permeability of the diaphragmatic lymphatics for particulate material. These vessels absorb blood from the peritoneal cavity with only a small loss of cell concentration. Nevertheless, the fluid part of the blood is more easily absorbed from the abdomen, for, at the end of six hours, the number of red cells in the peritoneal cavity had risen from 7,000,000 to 9,000,000 per c.mm. Sabin has shown that this blood acts like a foreign body, the cells being taken up by the macrophages. A considerable amount of blood is

still present in the abdomen six hours after injection, and is a good medium for the growth of micro-organisms. In some survival experiments on rabbits fatal septic peritonitis followed the injection of blood into the peritoneal cavity when rigid aseptic precautions were not taken. The danger of sepsis after intraperitoneal injections of blood must be emphasised, as it is much greater than after intravenous transfusions. Levi injected blood intraperitoneally in mice in the ratio of 10 c.cm. of blood to 450 g. body-weight of the animal. He found that, though blood was still present in considerable quantity in the peritoneal cavity after six hours, it had been completely absorbed in 48 hours.[3]

Intraperitoneal transfusion therefore is unlikely to be of value in the treatment of shock, collapse, and hæmorrhage, where an immediate increase in blood volume is desired. If intravenous transfusion is not possible, the injection of diffusible fluids into the subcutaneous tissues or the peritoneal cavity would seem more likely to meet with success. Where blood transfusions are indicated in the treatment of anæmia and the patient is not in extremis, intraperitoneal transfusion is a rational procedure and its simplicity may counterbalance the delay in the effects.

Results obtained from the study of the movements of ink particles and red cells injected into the peritoneal cavity are susceptible of a wider application. Abolition of abdominal respiration in peritonitis must check the absorption of bacteria and their non-diffusible products. The importance of the diaphragmatic lymphatics is already realised in the Fowler position, and absorption might also be diminished by avoiding tight binders and other factors likely to increase intra-abdominal pressure. It is probable that throughout the whole organism the entrance of particulate substances into the lymphatics is facilitated by pressure, and experiments now being carried out indicate that muscular contractions, the movements of the hollow viscera, and rough handling may be of the very greatest importance in determining the spread of metastases from malignant growths.

Summary.

1. Blood injected into the peritoneal cavity is absorbed by the diaphragmatic lymphatics and enters the circulation by the thoracic duct. 2. In the dog absorption is very slow, only one-sixteenth of the corpuscles being absorbed after six hours; the plasma is absorbed more readily. 3. The rate of absorption depends on the intra-abdominal pressure, and absorption is most rapid with vigorous respiration and abdominal muscles of good tone. 4. Absorption is promoted by massage of the abdomen, but it is doubtful whether massage forcible enough to produce beneficial increase in absorption could safely be applied to patients. 5. Much blood remains for many hours in the abdominal cavity and there is danger of infection. 6. Abdominal transfusion of blood is not likely to compare in value with the intravenous route in the treatment of shock and collapse; it seems a rational form of treatment for more chronic forms of anæmia.

THE FOUNDLING HOSPITAL SITE.—Difficulties have arisen regarding the proposed acquisition of a portion of the site of the Foundling Hospital by the Hospital for Sick Children in Great Ormond-street. Valuers appointed by the owners of the site and the governing body of the hospital were appointed to settle a fair price as between a willing seller and a willing buyer, but they have been unable to agree, and a proposal on behalf of the hospital that the matter should be referred to informal arbitration was not acceptable to the owners. A third valuer was then, by agreement, called in, who placed the market value at "probably not more than £450,000," but thought that, in view of the special advantages of the site for hospital purposes, the hospital would be justified in giving a maximum of £525,000. A firm offer of that amount was made but declined, and it would appear that, should there be no change in the situation, the building of blocks of flats on the site will begin almost immediately.

INDUCTION OF LABOUR WITH ANIMAL BLADDERS CONTAINING GLYCERINE.

BY G. F. GIBBERD, M.B., M.S.LOND., F.R.C.S.ENG.,
OBSTETRIC AND GYNÆCOLOGICAL REGISTRAR, GUY'S HOSPITAL.

MOST methods of inducing labour depend upon the introduction of some irritating foreign body into the uterus, and although this must always entail some degree of uncertainty and carry with it a certain risk of infection, yet, in the present state of our knowledge as to the cause of the onset of labour, it is the most reliable method that we possess. Irritating fluids have been followed by such grave complications that they have been entirely given up. Solid foreign bodies, such as Krause's bougies, Horrocks's bag, or a stomach-tube are used in the majority of cases. In the method here described a sterile animal bladder is introduced into the uterus and subsequently partly filled with glycerine. This acts as a foreign body. A proportion of the glycerine passes out of the bladder into actual contact with the uterine wall, and there acts as a mildly irritating fluid.

Method.

The apparatus consists of a small metal tube about 1 in. in length and provided with a series of circular ridges on its outer surface; this is attached to a piece of rubber tubing about 6 in. in length. A stilette, provided with a flexible steel wire, protected at the tip by a small knob, can be passed through the rubber tubing, so as to project about 5 in. beyond the end of the metal tube. A sterile bladder is then tied with silk to the metal tube. The stilette serves to stretch the bladder so that it can be introduced into the uterus in the same way as a Krause's bougie, without any handling of the bladder itself, and without its touching the vaginal mucous membrane. The flexible stilette is immediately deflected if it comes against the presenting part in the lower uterine segment, and thus there is no danger of injury to the fœtus or the uterus during introduction.

When the bladder has been passed through the internal os the stilette is withdrawn, and pure sterile glycerine is injected into the animal bladder through the rubber tubing by means of a large syringe. A clamp is then screwed on to the tubing to prevent escape of the contents of the bladder. With a large bladder, between 100 and 200 c.cm. and with a small bladder between 50 and 100 c.cm., are injected. As the bladder, tubing, and stilette are introduced in the same way as a bougie, it is nearly always necessary to have the patient under an anæsthetic, in order to ensure proper exposure of the cervix and full aseptic technique.

The method was introduced in 1901 by Baumm.[1] In the instrument devised by him a long metal tube was used instead of the rubber, but this caused considerable discomfort, since it projected from the vulva and had to be retained until the onset of labour. This very much restricted the patient's movements. The rubber tubing with a metal connexion for tying on to the bladder causes practically no discomfort, and the patient can adopt any attitude without difficulty.

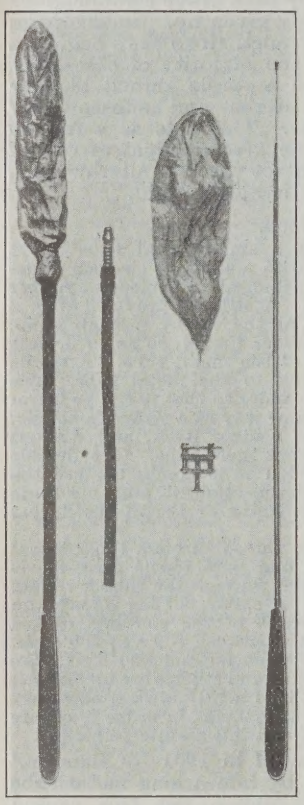
The animal bladders, ready sterilised and packed in alcohol, are obtainable in two sizes. Pig's bladders have a capacity of about 600 c.cm., sheep's bladders of about 150 c.cm. If a pig's bladder containing 150 c.cm. of glycerine is immersed in normal saline solution its contents will increase to about 500 c.cm. in 24 hours by the passage of fluid through the semi-permeable membrane. In addition to this a certain amount of glycerine passes out from the bladder into the surrounding saline. Such a bladder in the lower uterine segment gradually increases in size, so that the mechanical stimulus to labour increases in proportion to the time that the bladder remains in the uterus. The contact of a certain amount of free glycerine with the wall of the uterus still further stimulates the uterus to contract.

Possible Dangers.

Although the method was introduced over 25 years ago, it seems to have attracted little notice. Williamson,[2] in his review of the methods of induction, did not mention it, nor, as far as I am aware, is it noticed

by any other British writer on the subject. Recently it has been used by Scheffzek,[3] and by Sztehlo [4] in Germany, who speak well of the results obtained; and Druskin,[5] in America, considers it the best method of induction in the majority of cases. A sufficiently large number of cases have not yet been treated to warrant a definite opinion as to the dangers, but up to the present no serious dangers or difficulties have arisen. The two obvious ones are sepsis and the harmful effect of introducing glycerine into the uterus.

The danger of sepsis is present with any method depending upon the introduction of a foreign body into the uterus, but the technique employed enables animal bladders to be inserted with a minimum of possible contamination. The bladder and tubing, stretched by the stilette, can be introduced after the cervix has been exposed and steadied without coming into contact with the skin or the vaginal mucous membrane, and without being handled by the operator. It is certainly easier to introduce than a stomach-tube, and no more difficult than a bougie; furthermore, it occupies only the lower part of the uterus, and there is therefore no danger of separating the placenta, except when the latter is implanted in an unusually low position. The initial sterilisation of the bladder seems to offer no serious problem, since a similar problem has been successfully solved in the case of catgut used in surgical operations. A series of bacteriological tests on the bladders in use showed that they were sterile to all ordinary cultural tests.



Apparatus for induction of labour with animal bladders containing glycerine. The left-hand photograph shows the apparatus assembled and ready for introduction.

The incidence of puerperal morbidity has compared favourably with that following other operative methods of induction and, so far as it is possible to judge from a comparatively small number of cases, there seems to be no special danger of sepsis associated with the method.

There are two ways in which glycerine in the uterine cavity might conceivably do harm. In the first place, the mere local stimulation of glycerine in the uterus has, in some cases, been looked upon as an adequate cause of sudden death. Such accidents appear, however, to be unknown in ordinary obstetric practice, and, after all, stimulation of the uterus is the main object of all mechanical methods of induction. Furthermore, the injection of small quantities of glycerine is now widely used in the treatment of uterine infections, and apparently accidents do not occur. The danger of syncope can therefore be dismissed as purely theoretical.

There is no doubt that the absorption of large quantities of glycerine may cause considerable harm. An acute nephritis is said to follow large doses, and where glycerine has been injected between the uterine wall and the membranes with the object of inducing labour, severe toxic symptoms have resulted in a large proportion of cases. Where the glycerine is enclosed in an animal bladder, however, the danger of rapid absorption of a toxic dose of glycerine is avoided, since the fluid can only pass out very slowly, and never in sufficient quantity to cause poisonous symptoms. No cases have been met with in which there were any untoward signs suggestive of a toxic action.

Conclusion.

The method, therefore, seems to be free from any serious dangers, apart from those which must inevitably accompany any instrumental method of induction; in addition, the technique is simple and easily carried out. It is obviously unwise to draw conclusions from a small number of cases but, comparing the results with those obtained with bougies or the stomach-tube, the rapid onset of labour is a very striking feature of the animal bladder method. In some cases painful contractions have occurred as soon as the patient has recovered from the anæsthetic, and in the majority labour has definitely started within 12 hours. On the other hand, in one patient in whom the method was used there were no painful uterine contractions after four days; a stomach-tube was then inserted, but even then labour did not start for two days. In spite of an occasional case such as this (which may occur with any method) the bladder has given results which are sufficiently encouraging to warrant a more extensive trial.

Clinical and Laboratory Notes.

A NOTE ON THE TREATMENT OF ASCITES BY NOVASUROL AND AMMONIUM CHLORIDE.

By Sir John F. H. Broadbent, M.D. Oxf., F.R.C.P. Lond.,
PHYSICIAN TO ST. MARY'S HOSPITAL, LONDON.

My attention was called to the value of this method of treatment on a visit to the Mayo Clinic last year, and recently I have had the opportunity of testing this in three cases of ascites of different ætiology with such striking results that I thought them worthy of publication.

In 1925 L. G. Rowntree, N. M. Keith, and C. W. Barrier,[1] working at the Mayo Clinic, published a paper on Novasurol in the Treatment of Ascites in Hepatic Disease, and in the same year Keith, Barrier, and M. Whelan [2] published a paper on the Diuretic Action of Novasurol and Ammonium Chloride in Cases of Nephritis with Œdema. Previously, in 1920, Paul Saxl and Robert Heilig [3] had called attention to the efficacy of this method of treatment in cardiac dropsy. Novasurol is a double salt of sodium mercurichlor-phenyl oxyacetate with diethylbarbituric acid, and contains 33·9 per cent. of mercury. It is soluble in water and can be given by intravenous or intramuscular injections. It may be given in doses up to 2 c.cm. intramuscularly at intervals of three to seven days. Its tolerance should first be tested by giving 0·5 c.cm. intramuscularly.

Ammonium chloride is given by the mouth in divided doses up to grs. 150 in the 24 hours. I have found that 1 c.cm. of novasurol, followed by grs. 120 of ammonium chloride daily, was efficacious in producing marked diuresis. Novasurol alone or ammonium

[2] Ibid., p. 799.
[3] Wien. klin. Woch., 1920, xxxiii., 943.

chloride alone do not answer so well. The following are notes of the cases treated.

CASE 1.—A man, aged 54, was admitted to St. Mary's Hospital on April 23rd, 1928, with œdema of the legs and ascites.

History.—Noticed swelling of feet about six weeks ago followed by swelling of abdomen. In 1919 had operation for subphrenic abscess. Since then has done no work but has kept well. For the last nine years has drunk eight or nine small bottles of Guinness's stout every day.

On admission œdema of legs, ascites. Heart normal, Wassermann reaction negative. Passing very little urine, 16 to 20 oz. Girth, 36 in. Abdomen distended and tense, liver cannot be palpated. April 25th: Put on ammonium chloride grs. 15 every six hours; no result. 27th: Given 1 c.cm. of novasurol, followed by grs. 120 ammonium chloride in the 24 hours. Urine output rose to 66 oz. next day. The ammonium chloride was continued and the output of urine maintained. On the 30th œdema of legs had gone, but there was still some ascites, so another 1 c.cm. of novasurol was given intramuscularly. In the next 24 hours the urine output rose to 96 oz., all the ascites disappeared, and the girth was 32 in. There was no recurrence of ascites, and he was discharged a week later.

CASE 2.—A man, aged 51, was admitted to St. Mary's Hospital on April 6th, 1928, with œdema of legs and scrotum and ascites. The abdomen was tapped on April 10th and 19 pints of clear fluid were removed. Liver enlarged and hard, reaching down to umbilicus. Passed 14 to 24 oz. of urine. Œdema of legs and scrotum not much relieved by tapping. Fluid began to accumulate again in peritoneal cavity. April 23rd: 1 c.cm. of novasurol given intramuscularly and grs. 60 of ammonium chloride given by mouth next day. Urine output rose to 54 oz. 27th: 1 c.cm. of novasurol given as before, followed by grs. 120 of ammonium chloride in next 24 hours. Urine output rose to 112 oz. 30th: Same treatment. Urine output rose to 168 oz. All the œdema and ascites completely disappeared and the patient left the hospital feeling well.

This patient first attended for ascites in 1923 and, after several tappings at short intervals, had a Talma-Morrison operation performed by Prof. C. A. Pannett. After this he kept well till November, 1924, 15 months later, when he came in to be tapped again. He had been tapped at varying intervals since 10, 7, and 6 months, and recently at shorter intervals. He is not an alcoholic and the Wassermann test has been negative twice. The spleen is not enlarged, but at the operation the liver was very much enlarged, smooth, and firm. The ætiology of the condition remains obscure. He has since returned with recurrence of ascites, which again yielded to treatment by novasurol and ammonium chloride, when he passed 200 oz. of urine in 26 hours.

CASE 3.—A man, aged 44, was admitted to St. Mary's Hospital on April 23rd with œdema of legs and lumbar region and ascites. The abdomen was distended, the liver not felt. Heart normal, blood pressure 130/85. Incontinence of urine, which has been present for ten years. Urine spec. grav. 1008, alkaline, albumin under 1 per cent. (Esbach) and pus present; about 24 oz. daily. Œdema of legs began in February of this year. Wassermann reaction negative. April 27th: Given 1 c.cm. of novasurol, followed by grs. 120 of ammonium chloride in the 24 hours each day. Urinary output rose to 76 oz. on April 28th, and to 84 oz. on the following day. 30th: 1 c.cm. of novasurol again given and ammonium chloride continued. Output of urine rose next day to 128 oz., and was 84 oz. the following day. The whole of the œdema and ascites had now completely disappeared. The urinary output has since continued to be high, averaging from 40 to 60 oz. or more, and there has been no return of œdema.

The treatment of ascites by repeated tappings or ordinary diuretics is admittedly unsatisfactory. The explanation of the remarkable results obtained by the administration of novasurol and ammonium chloride is not clear. Rowntree, in addition, restricted the intake of water and salt, but this does not appear to be essential. Keith and Whelan came to the conclusion that the action of these diuretics was not limited to the kidney, but that extrarenal factors play an important part, and it is obvious that the transference of the fluid from the peritoneal cavity or the tissues to the blood stream is the primary difficulty and is essential for a satisfactory result.

Dr. George Curtis, of Chicago, in the Mayo Foundation Lecture this year on the Action of the Specific Diuretics,[4] described some experiments he had made on rabbits with the diuretic euphyllin. He found that during diuresis electrolytes form the greater part of the solids excreted in the urine, and that the chlorides calculated as sodium chloride predominate. The sodium chloride content of the blood also rises. He concluded that under the influence of the specific diuretics permeability changes are initiated in the tissues, resulting in a rapid passage of electrolytes, principally chlorides, into the blood stream from the tissues. These stimulate the kidney and pass into the urine in large amounts. He found that when diuresis did not occur the marked increase in chloride excretion did not take place.

[4] Proceedings of the Staff Meetings of the Mayo Clinic, April, 1928.

A CASE OF UNIVERSAL SUBCUTANEOUS SURGICAL EMPHYSEMA

ASSOCIATED WITH SPONTANEOUS PNEUMOTHORAX.

BY M. GERBER, M.B., B.CH. DUB.,
ASSISTANT MEDICAL OFFICER, KING EDWARD VII. MEMORIAL SANATORIUM, WARWICK.

UNIVERSAL subcutaneous emphysema associated with spontaneous pneumothorax is sufficiently rare to warrant description.

The patient, male, aged 19, was admitted to the Warwickshire King Edward VII. Memorial Sanatorium on April 2nd, 1928, with the signs and symptoms of advanced pulmonary tuberculosis in both lungs. He was rapidly going downhill, when at about 7 P.M. on April 12th he developed a very acute pain in the left axillary region. When seen soon after his breathing was rapid and distressed, and there was fairly well-marked cyanosis of the face with a frequent hacking and unproductive cough. The temperature was subnormal (collapse) and the pulse extremely rapid and almost imperceptible. The patient looked very distressed. A very superficial examination of the chest showed that the left side was hyper-resonant to percussion, and the apex-beat about an inch inside the right nipple line. The breath sounds on the left side were almost lost and of amphoric character, while on the right side numerous râles could be heard. A diagnosis of spontaneous pneumothorax was made.

It was decided to introduce a needle into the pleural cavity in order to allow air to escape, and thus reduce the intrapleural pressure. After a preliminary injection of gr. ¼ morphia with gr. 1/100 atropine, a pneumothorax needle was introduced into the pleural cavity through the fifth left intercostal space in the axillary line. The needle was connected by means of a piece of rubber tubing to the manometer of an artificial pneumothorax apparatus. The manometer showed an excursion of 0+10 cm. water with respiration, thus demonstrating that the endopleural pressure was definitely raised. The end of the tube which was attached to the manometer was disconnected and placed in a bowl of water. Immediately bubbles of air began to rise in the water, thus showing that air was passing out of the pleural space. The relief to the patient, as a result of this small operation, was almost immediate. The pulse became stronger and less rapid, and the breathing not so laboured. After a few minutes the intrapleural pressure was again taken and found to be −5+5 cm. water (mean atmospheric), as against the initial pressure of 0+10 cm. water. The relief to the patient was so striking that we decided to leave the needle in the pleural cavity over night, the needle being connected to the rubber tubing, and prevented from falling out by fastening it to the chest wall by means of adhesive plaster.

The next morning the patient had considerably improved. The intrapleural pressure was still −5+5 cm. water, and air was still passing out of the pleural cavity as fast as it came in. He had a slight subcutaneous surgical emphysema of the left chest wall around the site of the needle. That same evening the emphysema had spread all over his left chest wall and up the left side of his neck and face. The following morning he had the facies similar to that of a case of severe chronic parenchymatous nephritis. His face and neck were enormously swollen on both sides, and his eyelids were half closed. The emphysema extended upwards as far as his forehead. There was no emphysema of the scalp. He had subcutaneous emphysema of the chest wall on both sides, both front and back, likewise the abdominal wall, upper limb as far as the carpo-metacarpal joints, and the left lower limb as far as the ankle were all emphysematous, while in the right lower limb it extended as far as

the knee-joint. The whole back all the way down presented crackling emphysema.

The patient was severely distressed and his breathing very shallow. As death seemed not far off, the needle was removed from the pleural cavity. He died in the early hours of the next morning (April 14th).

At the autopsy performed by Dr. F. R. Heaf both lungs were found to be extensively diseased with a broncho-pneumonic infiltration and a large cavity at each apex. There was a perforation of the visceral pleura of the left lung about 3 in. from the extreme apex, 5 mm. in diameter, and extending 7 mm. into the lung tissue. The perforation was in all probability due to rupture of a superficial caseous focus through the visceral pleura. A very dense adhesion attached to the visceral pleura near the site of the rupture, by tension of the lung tissue, probably played some part in causing the perforation.

THE EFFECT OF THE PROLONGED USE OF INSULIN ON THE SUBCUTANEOUS TISSUES.

By R. D. Lawrence,* M.D. Aberd., M.R.C.P. Lond.,
CHEMICAL PATHOLOGIST, KING'S COLLEGE HOSPITAL.

Various writers have dealt with unusual effects that may occur in the subcutaneous tissues as the result of insulin injections. These are: (1) irritative inflammatory reactions [1] which occasionally occur at the commencement of treatment, and (2) areas of local fat necrosis [2] resulting from the continued injection of insulin into one small area. The first type of reaction may be temporarily troublesome and cannot be avoided, as it is an idiosyncrasy, probably of an allergic nature, but it very rarely persists more than a few weeks. Local fat atrophy only occurs when the injections are persisted with too frequently and for too long a time in one place, and never occurs if the patient is warned to distribute the doses properly. The atrophic areas may fill up again normally with fat when the injections are inserted in another place.[3] In most insulin cases, however, these effects are not seen, and it has seemed of interest to examine the usual effects of insulin properly administered in two doses a day continuously since its introduction five years ago. This has been done in a male patient of 35 by radiography and microscopy of various pieces of skin and subcutaneous fat.

Immediate Effects.

All the injections have been administered deeply into the subcutaneous tissues, just superficial to the deep fascia rather than immediately under the true skin. In this way pain is minimised. Indeed, if the needle is a fine one, so that it is possible to get in between the pain nerve terminals, the prick is not felt at all. The acid reaction of the insulin, however, always causes some stinging when injected into fresh tissues, but this disappears entirely when the tissues are accustomed to insulin by a few doses. Thus the injection may be entirely painless. This stinging in newly used tissues often makes the patient hesitate to shift the injection to another area after a week or two, and in this way fat atrophy may occur. Localised subcutaneous œdema always follows the injection and lasts 18–36 hours before subsiding. Intradermic injections are always painful and produce a pigskin appearance of the skin as well as excessive stinging, and I have seen aseptic necrosis. Injections into muscle cause no initial stinging, but are apt to be painful for the next 24 hours when the muscle is used. There is evidence that they may produce local necrosis of the muscle.

Permanent Effects.

Three different areas of skin were examined by palpation, by excision of the skin and subcutaneous fat for microscopy, and by X rays. They were: (1) an area from the thigh which had never been used; (2) an area from the left forearm which had received no injections for three years but had been almost continuously used during the preceding two years; and (3) an area of the thigh which had been frequently used lately.

On palpation the skin and subcutaneous tissue of the left forearm felt considerably thicker and more fibrous than the part of the arm which had never been used. In making the incision the knife met with considerable fibrous resistance, which was still more noticeable in the area frequently and recently used, where œdema was also present. It was noticeable (painfully so!) that these tissues could not be anæsthetised with novocaine injected into the surrounding areas.

Microscopy.—Dr. E. ff. Creed has kindly furnished the following report:—

"The histological changes are comparatively slight. The sections from the arm (used three years before) show fibrous strands extending down from the corium into the subcutaneous fat. The strands divide up the fat into coarse lobules. Infiltrating the fibrous tissue, especially in the neighbourhood of the vessels, are lymphocytes and histiocytes with a few plasma cells and one or two eosinophiles (more of the latter are present than in the section of the normal skin). The sections from the hip do not show the down-growth of fibrous trabeculæ, but there is some infiltration in the neighbourhood of the vessels similar to that seen in the arm sections."

Radiological examination with a soft tube showed very little change in the subcutaneous tissues, but suggested a slight increase in fibrous tissue just superficial to the fascia lata of the thigh. Another patient, however, in whom the injections had been less widely distributed, showed considerable increase in fibrous tissue and some suggestion of rarefaction in the muscle immediately underlying the fibrous fascia lata. This patient has always pushed in the needle at right angles to the skin, as deep as it would go, as she found that this minimised the stinging. It is, therefore, very probable that many of the injections reached the muscles and caused a slight rarefaction. Bowie and Robinson,[4] in experiments on rabbits, showed that whereas insulin caused only some œdema in the subcutaneous tissues and no cellular infiltration, it produced necrosis and rarefaction with a cellular infiltration in the muscles. As far as the evidence in this case goes, the same appears to happen in human muscle.

Summary.

The effect of insulin injections, properly distributed in the subcutaneous tissues, is very little over many years. The temporary effect is always an œdematous exudate, but, when this passes off in 18–36 hours, no permanent effect is left, except the tendency to slight fibrosis in the subcutaneous fat with some increase in the connective tissue cells. Intradermic and intramuscular injections are inadvisable and may produce focal necrosis. Prolonged injections into a limited area may produce marked fibrosis and fat atrophy.

I am indebted to Mr. H. C. Edwards, F.R.C.S., for the excision of the skin areas, and to Dr. Graham Hodgson for the radiological examinations.

* Working on insulin for the Medical Research Council.

Lord Mayor Treloar Cripples' Hospital.—The cost of keeping in order the many wooden buildings of this institution at Alton, in Hampshire, has become so heavy in consequence of their increasing age that it has been decided, as means permit, to replace them by permanent structures. The hospital will come of age in 1929, and most of the buildings were erected nearly 20 years ago. The cost of repairs at present exceeds £5 per bed per annum.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF EPIDEMIOLOGY.

A MEETING of this Section was held on June 22nd, Dr. S. MONCKTON COPEMAN, F.R.S., the President, being in the chair. Dr. J. A. GLOVER communicated Some Observations on

Nasopharyngeal Epidemics in Public Schools.

He declared that over 80 per cent. of school-sickness—judged either by the actual number of cases or by the time lost—was transmitted by "droplet" infection, otherwise termed spread by nasopharyngeal ejections. He doubted whether the importance of nose-to-nose and mouth-to-mouth infection was even yet realised. The public schools of England offered a unique field for epidemiological study, yet, except by a few observers, the material had not been used to good advantage. Surg.-Commander S. F. Dudley, in two reports on the Royal Naval School at Greenwich, published by the Medical Research Council, made a most important contribution to epidemiology, and the work of Clement Dukes, at Rugby, was classical. Dukes showed, in 1905, that the number of cases of infectious disease was increasing, the increase being doubtless due to greater care in the homes in preventing such diseases, so that the boys or girls reached the public school unprotected by previous attacks. Part of the increase, however, was apparent only. The absence of scarlet fever in the great public schools was remarkable, especially in view of the fact that the tonsillitis at a particular school investigated was mostly due to infection by hæmolytic streptococci of the scarlatinal type. Since the 1918 epidemic, said Dr. Glover, there had been a greater prevalence of influenza; more boys were now sent to public schools, with a resultant over-crowding of class-rooms and dormitories. A possible factor, too, was the greater attention now being paid to what could be termed "febricula." Influenza had occurred in epidemic form in three of four years in Lent term, and once there was so much diarrhœa and vomiting that the term "gastric influenza" was justified. In four years the admissions to the infirmary of one of our public schools were: influenza, 28 per cent.; feverish cold, chill, pyrexia, and bronchial catarrh, 15 per cent.; tonsillitis, 20 per cent. of all admissions. Dr. Glover said that the character of the epidemic was a good guide in distinguishing whether or not an epidemic of febrile catarrh was influenza, and gave a better indication even than the clinical features of the actual cases. True influenza epidemics were of an explosive character. High attack-rates in schools were very common; in certain houses this rate was as high as 95 per cent. There seemed to be little correspondence between the height of the attack-rate in an influenza epidemic and the prevalence of complications—i.e., such as pneumonia and otitis media; the latter, indeed, were secondary epidemics, which might or might not occur. At Eton, out of 717 uninoculated boys, 294 were attacked by influenza in an epidemic, while of 302 inoculated 149 were attacked. At Haileybury, out of 315 uninoculated 67 were attacked, and of the 215 inoculated 34 were attacked. L. R. Lemprière had said that true influenza was beyond the control of the school medical officer, but this should not apply to that persistent condition in schools which went under the name of pyrexia of unknown origin (P.U.O.). In the great influenza epidemics of 1918 and 1919 there seemed to be evidence that a previous attack did confer some immunity against one or more of the subsequent waves of infection. Thus, at King's College School, Cambridge, where 100 per cent. of the boys were attacked in the epidemic of July, 1918, none were attacked in the epidemic in the November of the same year, though 58 per cent. of them were again subjects of the disease in the following March. A similar sequence was noted at Rugby School. In 1922, Dr. A. L. Simey considered that partial and temporary immunity was conferred by an attack of febricula against influenza, and by influenza against febricula. It would be of interest to know whether Dr. Simey still thought so, since Dr. Glover's own view was that no immunity was so conferred, rather that the reverse was the case. It seemed to be the general opinion that epidemics of influenza could not be prevented by vaccines; if these were to be used at all, it should be before the danger period—i.e., not later than November. With regard to prophylactic measures other than vaccines, Dr. Glover strongly believed that more intensive measures at the beginning of each Lent term would well repay school authorities, and he quoted striking cases of mischief resulting from boys having returned to school from home while in a highly infectious state. No work, he thought, should be done in school before breakfast in January, February, and perhaps March, though he had no objection to a sprint in the open-air. He was sceptical as to the efficacy of nasal douching and spraying, though at one school their use seemed to have been definitely successful. As to baths, a proper skin reaction was one of the great defensive ramparts of the body, and hence a warm bath or shower should always be immediately followed by a cold shower, to tone up the skin. Diet was also important, especially in respect of oranges, vegetables, salads, and watercress.

He believed that by far the chief communication of infection of boy to boy took place in the school dormitories, though in one school epidemic investigated the mischief seemed to have been wrought in one of the common rooms which was used by the boys for a variety of purposes, mostly with the windows closed. He has seen a good deal of over-crowding of beds in large public schools. There should always be at least 3 ft. of space between the edges of separate beds, and an open space of 700 cu. ft. for each occupant. Not only cross, but adequate through ventilation was essential. One epidemic of persistent sore-throat investigated by the speaker was apparently due to a non-hæmolytic form of strepto-coccus; possibly there was superadded sanitary defect. Only Grade A milk should be used; failing that, all milk used in schools should be pasteurised.

In conclusion, Dr. Glover suggested that medical officers of schools might profitably investigate a number of matters which still remained unexplored, with the view of increasing good health at the schools. Some of these were as follows: The epidemiology and bacteriology of otitis media in relation to influenza and febricula; the relative sickness-rates of boys' and girls' schools, and of day and boarding-schools; the incidence of droplet infections upon children whose tonsils had been enucleated and adenoids removed, compared with that in children who had not been so dealt with; the use of the uniform system of medical record adopted by the Association of School Medical Officers; the methods of encouraging the school-boys and girls to keep fit; the possibilities of intensive prophylaxis during the first half of the Lent term.

Discussion.

The PRESIDENT said he was struck by the large proportion of cases of disease which occurred in schools as a result of "droplet" infection. He was also concerned about the remarks as to the efficacy of the vaccine treatment of influenza. Soon after the war he had been entrusted by the Ministry of Health with an intensive campaign in the Universities of Oxford and Cambridge, because it was feared there would be a large incidence of influenza between the ages of 18 and 25. He was allowed five minutes' talk to the men just before their lunch, and, as a result, over 5000 inoculations against the disease were performed in these universities. He did not know the exact statistical results, but he hoped they

were better than those which Dr. Glover considered usual. It would be agreed that school dormitories were the most likely places for infection to occur, especially if the ventilation was bad. However, one outbreak of diphtheria which he had studied, had clearly originated and been extended in one of the class-rooms, the cases having occurred centrifugally around one in the room. Dietary in schools was a very important matter.

Surg.-Commander DUDLEY expressed his general agreement with Dr. Glover. It was true that the minor infections in a school—tonsillitis, catarrh, influenza—constituted 75 per cent. of the whole, but the time lost was not so great as that wasted by the acute specific diseases. Whatever measures, such as vaccines, might be adopted in schools to counteract or prevent the minor ailments, he believed these were sure to occur. As to the question whether acute disease occurred in a school mostly among residents or non-residents, the experience at Greenwich School was of interest. This school took both residents and day-boys, all the boys playing the same games and attending the same classes. In three years one in every three of the residents had diphtheria or scarlet fever, but not one of the day-boys had either disease in the same period.

Dr. G. E. FRIEND said that at his school the admissions to the infirmary of cases of obscure pyrexia, tonsillitis, and febricula—excluding other droplet infections—amounted to 36 per cent. of the whole. He felt convinced that no preventive measures in schools would make a great difference to incidence, but the lines recommended by Dr. Glover were undoubtedly sound. Mass inoculations of vaccine to large numbers of boys was a matter to be approached with great caution, though once he had done inoculation to 65 per cent. of the boys, and another time 90 per cent. The insistence on the production of a certificate of good health before a boy was allowed to return to school, as at Rugby and Haileybury, resulted in the absence, through colds, of a considerable number of boys at the beginning of term. At Christ's Hospital he had proved that infection did not occur in the dormitories, where the spacing in the new building was all that was required. Epidemics spread mainly through the class-rooms.

Captain R. M. MAY spoke of the difficulties of attempting to carry out ideal methods for improving the health in schools. For the spread of infection he blamed chiefly the dormitories. An intensive campaign at his school against sore-throat, catarrh, and tonsillitis, during the last four years, with an expert to treat or remove tonsils and adenoids, had led to a great diminution of those affections.

Prof. MAJOR GREENWOOD said that the incidence of second attacks of influenza in schools was a matter of interest. The report of the Ministry of Health on the influenza epidemic, which dealt with such large figures that random errors were practically negligible, showed enormous differences in the proportions of boys who were attacked in the summer and again in the autumn. It seemed to point to different immunising qualities of different strains of organisms. The great point to remember when dealing with closed communities was that so long as non-immunised individuals were introduced to the herd, no measure of prophylaxis was likely to be effective as a preventive. Long series of observations on large numbers was needed, such as could be made in mice, to justify satisfactory epidemiological conclusions.

Dr. DALRYMPLE-CHAMPNEYS spoke of his visits of inspection to the chief public schools of the country. He said he found overcrowding in dormitories very common, and sometimes the architect was responsible for the best of the space not having been utilised in the dormitories. He pleaded for a much more generous cubic space in dormitories and a greater space between beds.

Reviews and Notices of Books.

PSYCHOLOGY.

Directing Mental Energy. By Dr. F. A. P. AVELING, M.C., Ph.D., Lecturer in Psychology, King's College, London. University of London Press. 1927. 8*s.* 6*d.*

Dr. Aveling's study of the directing of mental energy gives in a concentrated form all the work that has been recently done on the application of psychology to industry and occupation. It succeeds in bringing home to us what every observer of sociological phenomena must have noted, the lamentable wastage due to psychological maladjustments of members of a complex social organisation. The book is really a treatise on economic psychology. General psychology demonstrates the process of the human mind, and economics deals with the phenomena of exchange of commodities and the way in which the human unit is concerned in these interchanges. In the past psychology was too aloof from affairs of the world to concern itself with the manifold ways in which the human mind affects and is affected by economic situations. Economists in their turn were apt to regard the human subject as an unchanging unit in economic affairs—a mere shuttle which carries the thread of industrial activity across the loom of the economic state, carded with the pattern of economic laws. When efficiency became the cry of the industrialist every effort was made to eliminate superfluous processes, and it was soon found that it was not the processes alone that were important, but the way in which man was affected by them. Output was found to be influenced by the physical and mental fatigue of the workers, and the worker himself was frequently found to be psychologically unsuited to certain forms of work. Thence grew up the science of industrial psychology and vocational testing. Dr. Aveling deals with the root problems of both these departments; and, although the book is comparatively small, it discusses very fully the details of methods of testing.

Dr. Aveling has given us a readable work, which can be studied by medical men with profit—since practitioners, as well as mental specialists, are every day meeting conditions of disturbed mental and physical functions which can only be understood if the economic situation of the patient and his reactions to such situation are taken fully into account.

Mind: Lectures delivered at King's College, University of London, in various subjects. Edited by R. J. S. MCDOWALL, D.Sc., M.B. London: Longmans, Green and Co. 1927. Pp. 316. 8*s.* 6*d.*

THESE essays, bound together by a single purpose—that is, the establishment of the concept of mind as a governing principle in the sciences—are yet entirely independent of one another in that each writer, a specialist in his own department, has thought out his thesis without collaborating with the others. While Prof. Julian S. Huxley attacks the problem of biology from a psychological evolutionary point of view—seeing in mind and value the final emergents, Prof. R. J. S. McDowall sees physiology frankly as a mechanist. Dr. F. A. P. Aveling's paper is designed to demonstrate the nature of the laws of psychophysics, and Dr. J. A. Hadfield finds in psychotherapy and the phenomena of psychopathology definite evidence of mental agency as potent as the activities of the physical world. Prof. Linderman orientates the subject in dealing with physics to the realm of logic and shocks our self-complacency by stating that physics is not dogmatic. but takes its stand as the basis of working categories rather than ultimates, the nature of which can never be assured. Thus, whatever indefinables we use—a stable world of physics can be built—whatever set we choose is purely a mental bias. Prof. Linderman's essay is one of scientific scepticism and

perhaps the best in the book. The other essays are on philosophy by W. R. Matthews, education by Dover Wilson, æsthetics by R. G. Collingwood, anthropology by C. G. Seligman, and sociology by Prof. L. T. Hobhouse. Prof. Seligman seems to be influenced by the extravert-introvert distinction in racial types, while Prof. Hobhouse epitomises his well-known views on the importance of mind in social evolution. Altogether an interesting collection of essays.

Psychology of Character. By A. A. ROBACK. London: Kegan Paul and Co. 1927. Pp. 566. 25*s*.

FROM time immemorial the study of character has occupied the minds of philosophers and moralists. With each advance in scientific knowledge of man in his mental, moral, and physical aspect the study has been influenced by the progress made and by the theories advanced to explain the nature and varieties of human character.

Dr. Roback's erudite and informative work is an attempt to deal with all the material bearing upon the subject of character, and to judge from his references he seems to have explored relevant sources of philosophy from the Talmud to the latest excursions of the Gestalt theme of Germany. The author is to be congratulated on having kept his head above the flood of literature and on keeping a keen outlook for any land upon which the scientist may set an assured foot. Some philosophers are impressed by the influence of physical phenomena on character, others seek, by dividing the human mind rigidly into emotional and intellectual aspects, to explore its machinery. These theories do not exclude one another, but until they are more closely correlated, the establishment of an orderly edifice of a science of character will not be possible.

FOODS: THEIR COMPOSITION AND ANALYSIS.

Seventh edition. By WYNTER BLYTH and HENRY EDWARD COX. London: Charles Griffin and Co., Ltd. 1927. Pp. xxv.+619. 38*s*.

THOSE familiar with Dr. Cox's book on Chemical Analysis of Foods will welcome his association with the seventh edition of this classical work. The characteristics of the original book have been maintained, some chapters have been rewritten, many new sections written, and some obsolete matter omitted. The book is divided into nine parts. Part I., which deals with the history of adulteration, differs only from the text of the last edition in that it is brought up to date and includes: the Milk (Special Designations) Order, 1923, the Public Health (Preservatives, &c., in Food) Regulations, 1925 and 1926, and the Milk and Dairies Consolidation Act, 1915. Part II. is devoted to a description of a few special forms of apparatus and, so far as it goes, is useful. A considerable amount of Part III., which deals with the carbohydrates, has been rewritten; Pavy and Gerrard's processes for the volumetric estimation of sugars have been omitted, while the methods devised by Ling and Rendel, and Lane and Eynon, are added, also the iodometric method. The section on honey is well revised. There is an obvious error on p. 140, which, curiously enough, has escaped detection in the last two editions; from the text it would appear that the higher the specific gravity of a 10 per cent. solution of treacle the more *water* the treacle contains. King's new method for the detection and estimation of pectin and agar-agar are given; sections on improvers and bleaching agents in flour, infants' foods, baking-powder, and egg substitutes have also been added. A fuller discussion on the report of the Departmental Committee on the treatment of flour might have been provided with advantage.

Part IV. deals with the important subjects of milk, condensed milk, butter, margarine, cheese and lard. The chapter on milk is disappointing; there is too much adherence to the older text. More information should have been offered on the variation in composition, including a résumé of the statistical studies of Tocher. We miss any allusion to the method of Monier Williams for the estimation of boric acid in liquid eggs and other foodstuffs. Bacteriological technique for the examination of Certified Milk, "Grade A" milk, &c., is set out, but other methods of judging the cleanliness of milk are ignored. The sections on the pathogenic bacteriology of milk are the weakest in the book, being quite out of date. Klein's work on scarlet fever and milk is retained in its original form, and no recent work on this subject is mentioned. The opinion of Koch on the transmission of bovine tuberculosis to man is given as if the question were as still unsettled as it was in 1901. Important matters such as the presence of Salmonella bacilli in milk, cellular elements in milk, and the valuable work on streptococci in mastitis cases find no mention. It would have been better to omit discussion of the pathogenic bacteriology of milk, unless the authors were prepared to give an accurate and modern account of this important subject. Details of the methods of analysis of condensed and dried milk are clearly given, and the chapters on butter and margarine contain useful new sections.

Other parts of the book deal with the chemical analysis of various foods and beverages, and contain much useful chemical information. These sections are well up to date and include new methods such as those for the estimation of caffeine, theobromine, shell in cocoa, the new original gravity table of Thorpe and Brown, and Monier Williams's electrolytic apparatus for the estimation of arsenic. A useful chapter deals with the chemical analysis of water, but the account of bacteriological methods is meagre and ignores recent work, such as that on the differentiation of coliform organisms. To the medical man the book is rather a disappointment, although Dr. Cox has certainly effected great improvements. We trust that in the next edition more of the older matter will be deleted, and that the space saved will be allotted to new sections upon such foods as eggs, flesh foods, meat extracts, canned foods, fruits and fruit juices, which subjects are either omitted or inadequately treated.

SPECIAL GYMNASTICS.

Das Münchener Sonderturnen und andere Wege zur Körperlichen Ertuchtigung. Edited by Dr. FRITZ LANGE, o.ö Professor der Orthopädie an der Universität München. Munich: J. F. Lehmann. 1928. With 78 illustrations. Pp. 106. M.6.

FIVE writers have assisted Prof. Lange in the preparation of this handbook, the subject of which is special gymnastics and other means of procuring sound bodily development. In such a work a good deal of space is necessarily taken up with the consideration of faulty posture and its correction, a subject which has occupied a great deal of space in orthopædic works published in the United States of late years. The work of Goldthwait and his colleagues does not, however, seem to have attracted much attention from Prof. Lange. Prof. Eugen Matthias writes on the means of bodily exercises, Dr. Karl Gebhardt on pupils' exercise camps, Dr. Joseph Trumpp on problems of nutrition, the Editor discusses defects of posture and bodily exercises, Dr. Ludwig Aubry special gymnastics, and Prof. Georg Hohmann scoliosis and deformities of the thorax. These six authors, among them, cover a good deal of ground. The essay by Dr. Aubry which, presumably, gives its name to the book, contains illustrations of various types of faulty posture and of exercises for their correction. These, unlike the old-fashioned German gymnastics, involve the use of the minimum of apparatus, and seem well designed to achieve their purpose, although we have received the impression that faulty posture and its treatment is really more a problem of nutrition (in its widest sense) than exercise. It is more likely to be the result of departure from physiological normality than its cause. Knock-knee of such a severe grade as

that shown in Fig. 30, however, can hardly be classed as a mere faulty posture and certainly is not to be cured by gymnastics alone. The book is well illustrated and contains a good many useful hints for teachers of remedial exercises and gymnastics.

PRACTICE OF UROLOGY AND SYPHILOLOGY.

A Surgical Treatise on Genito-Urinary Disease and Syphilis. Fourth edition. By CHARLES H. CHETWOOD, M.D., LL.D., F.A.C.S., Attending Urologist and Director of Service, French Hospital, New York. London: Humphrey Milford, Oxford University Press. 1928. Pp. 879. 42*s*.

THE American School of Urology is prolific in its publications, and a great many new works on genito-urinary diseases have appeared in the last ten years. Dr. Charles Chetwood's "Practice of Urology" is, however, an old friend in a new garb. It has reached its fourth edition, and has celebrated that event by being clothed by a new publisher. Numerous illustrations have been added and the text has been extended so as to include recent advances. Useful paragraphs appear on the important subject of regional anæsthesia. Amongst other methods that have found recent favour with urologists are those based on nerve blocking. Dr. Chetwood's description of trans-sacral and cordal block will, therefore, be found to be a welcome addition to his work. The last chapters, as before, deal with the diagnosis and treatment of syphilis, and here new paragraphs appear on the subject of malarial and protein therapy. Dr. Chetwood's book is well known and its popularity should increase with the appearance of a new and up-to-date edition.

CILIARY MOVEMENT.

By J. GRAY. Cambridge University Press. 1928. With 105 figures. Pp. 162. 10*s*. 6*d*.

THIS latest volume of the Cambridge Comparative Physiology is at least as interesting as its predecessors. Cilia in one form or another occur throughout the animal series except in nematode worms and insects; they are responsible for the movements of spirochætes and trypanosomes at one end of the scale and for the protective evacuation of bronchial mucus with its entangled foreign particles at the other. Since this discovery by Leeuvenhoek, they have excited a great deal of observation and experiment, of which Mr. Gray gives an admirable and well-illustrated account. In his discussion of the intimate mechanism of ciliary movement he inclines to the view that the alternate bending and straightening are produced by alterations in the distribution of water in the filament, much in the same way as a strip of paper moistened on one side will curl over and then become straight again as it dries. Another chapter which attracts attention is that on the coördination of the movement on a mucous membrane; of this there is at present no simple explanation. In some cases it is under nervous control, in other cases it certainly is not.

TUBERCULOSIS.

L'infection bacillaire et la tuberculose chez l'homme et chez les animaux. Third edition. By A. CALMETTE, A. BOQUET, and L. NÈGRE. Paris: Masson et Cie. 1928. Pp. 883. Fr.125.

A THIRD edition of Prof. Calmette's book has appeared within six years of its predecessor—with an English translation of the second French edition intervening. No other book that we know covers quite the same ground, and we should place it in a small and select company of books which together contain the law and the prophets in tuberculosis. This new addition has lengthened the work to the extent of more than 200 pages. Besides numerous small editions, such as accounts of new staining reactions, there are new sections on the chemistry of the tubercle bacillus, the standardisation of tuberculin, the so-called filter-passing virus, serum diagnosis tests, and anaphylactic phenomena. The chapter on vaccine therapy has been recast and a full review of B.C.G. vaccine added. It is a pleasure to find a subject index in this edition. Prof. Calmette and the two new collaborators with whom he has done so much recent research, Drs. A. Boquet and L. Nègre, are to be congratulated on the production of a sound piece of constructive work. We hope one day it will be accorded a better binding.

NEOPLASMS.

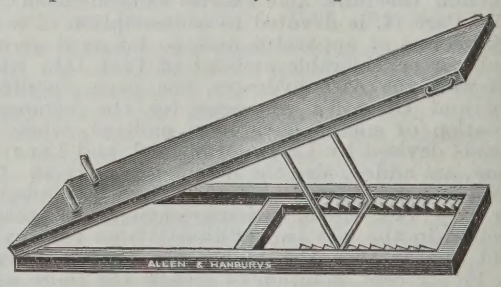
The Pathology, Diagnosis, and Treatment of Neoplasms originating in the Walls of the Urinary Bladder. A Monograph based on the Buckston-Browne Prize Essay for 1927. By LIONEL R. FIFIELD, F.R.C.S. Eng., Surgical First Assistant and Registrar and Chief Assistant in the Genito-Urinary Department, the London Hospital; Demonstrator of Anatomy, the London Hospital Medical College. London: H. K. Lewis and Co., Ltd. 1928. Pp. 94. 7*s*. 6*d*.

THIS monograph by the late Mr. Lionel R. Fifield was based on the essay with which he won the Buckston-Browne Prize for 1927, and the proofs had only just been passed by him when the tragedy occurred which terminated his life. The book begins with a thoughtful report and analysis of 306 consecutive clinical cases of growths of the bladder admitted to the wards of the London Hospital, all of them examples of the more common varieties—papilloma and carcinoma; and, after a short reference to the rarer growths, concludes with a chapter on original experimental research on transplantation of the divided ureter. Perhaps the best part of the book is the chapter on diagnosis, which is particularly clear and good, but the whole gives a well-rounded account of an interesting subject and shows that a painstaking worker and investigator has been lost to the profession.

New Inventions.

A FRAME FOR THE TRENDELENBURG POSITION.

IT is not infrequently desirable that patients should be kept in the Trendelenburg position after operation, and especially during the interval which elapses between removal from the operating-table to bed. The light wooden frame, here illustrated, can be placed on a trolley, the patient transferred



to it from the operating-table, and, on raising the foot-end of the frame, the Trendelenburg position can be maintained by means of a graduated ratchet support. The patient in this manner is taken to the ward or room, where the bed is ready, propped up at the foot. The frame should prove invaluable in hospitals and nursing homes where no facility exists for keeping the patient in the required position.

The apparatus was made for King's College Hospital, and it can be obtained from Messrs. Allen and Hanburys, Ltd., 48, Wigmore-street, W.

CECIL HUGHES, M.B., B.S. Lond.

THE LANCET.

LONDON: SATURDAY, JUNE 30, 1928.

THE LATER PHASES OF ENCEPHALITIS.

THE more complete our knowledge of chronic epidemic encephalitis, the less hopeful seems the outlook for those unfortunate enough to fall victims to the infection. A few years ago it was believed that quite a large proportion of those patients who survived their acute attack could be regarded as completely recovered and unlikely to suffer any ill effects. But time has shown that this prognostic valuation was much too optimistic, and there is now abundant evidence that very few of those affected escape without some resultant trauma, be it physical or mental. Some authorities, such as Dr. GARDNER ROBB, of Belfast, and Dr. ERIC PRITCHARD, of Indiana, are inclined to doubt if any patient is left without some relic of his illness, and though this is probably an exaggeration it is sufficiently near the truth to support the contention of those who advocate a very special consideration of the administrative and medical problems involved.

There is published to-day, under the auspices of the Ministry of Health, a report of an Inquiry into the After-histories of Persons Attacked by Encephalitis Lethargica, by Dr. ALLAN C. PARSONS. This comprises an analysis of 3500 patients notified to the Ministry between 1919 and 1926, and it shows that if 100 cases are investigated, say three years after the primary illness, the average findings will be as follows: Patients who have survived without serious consequences, 25; patients who have died, 35; patients who have become more or less disabled in mind or body, or both, 40. There is little doubt that we are dealing with a progressive disease which has little or no tendency to cure, and that the longer any series of cases is followed up the fewer become the patients in whom no disability can be found. The mental consequences of the disease are if anything more distressing than the physical, and their nature can be judged from a paper by Dr. P. K. MCCOWAN and Dr. L. C. COOK, published on p. 1316 of our present issue, in which a praiseworthy attempt is made to present a more or less orderly classification of the types of mental disorder which may be encountered. It is found that the mass of individual mental symptoms, usually described as protean and unclassifiable, can in fact be reduced to quite a fair degree of order under a few groups resembling well-recognised forms of mental disease. The description of the encephalitic temperament given by MCCOWAN and COOK seems to be applicable to most chronic encephalitics, quite apart from those psychotics who have come specially under their notice, and there is much to be said for their attempt to explain it in terms of regression. The reduction of the different forms of reaction shown by the encephalitic patient to various forms and degrees of this same mental mechanism of regression makes for a clearer understanding of their behaviour and other mental symptoms. It is only by close and prolonged observation of individual cases that we can hope to gain a true insight into the mentality of these unfortunate sufferers, and it is here that the various encephalitic units instituted throughout the country have valuable opportunities for research. This theory of regression advantageously groups the behaviouristic type of encephalitic with those suffering from other forms of mental disorder, which is preferable to regarding moral and mental changes as two forms of possible sequelæ as distinct from each other as from the physical sequels. It has long been recognised that encephalitis has varied in its manifestations from year to year, a particular symptom being much commoner at one time than another. Probably the most striking recent example of this is the present wane of respiratory phenomena and the increase in frequency of tonic eye spasms or oculogyric crises. Less spectacular but equally striking is the fact brought out by the Registrar-General's returns, which show that the number of deaths occurring at later stages of encephalitis is becoming larger each year, so much so that while in 1921 the percentage of deaths occurring between 4 months and 6 years after onset was 4·2, in 1926 it was 28·8.

The problem of the chronic encephalitic is likely to be with us for many years to come, and especially in the domain of administration should the Ministry of Health's report prove of value. It endeavours to appraise the amount of sickness attributable to the continued effects of encephalitis lethargica, and the estimates and various departmental reports which it includes should be useful in solving such administrative problems as the provision of institutional accommodation or employment centres and the adaptation of existing institutions to meet the needs of special cases. The passage of the Mental Deficiency Act, 1927, will doubtless prove of much value in dealing with certain troublesome patients, and we understand that already the Board of Control have set aside special villas at their State institution at Frampton for cases of this type. This, however, leaves untouched what is probably a much more important question, certainly numerically—namely, the disposal of the ordinary chronic encephalitic, and especially of poor patients, not able to remain at home. This is a problem which concerns ultimately the various public authorities, but they would doubtless welcome advice from medical men whose experience qualifies them to throw light on this difficult subject. It is surprising to find how many agencies and public departments are involved in looking after even a single encephalitic patient. Thus, apart from the local authority or hospital which deals with the initial disease, the patient may subsequently be dealt with by some education authority, the Home Office, poor-law guardians, the Board of Control, or the Prison Department. These authorities are unanimous in stating that many of the patients are not suitable for their respective institutions, and Dr. PARSONS'S statistics should make it easier to estimate the numbers for whom existing measures, institutional and other, are at present inappropriate.

EPIDEMIC JAUNDICE IN GREAT BRITAIN.

SINCE the classical description of this disease by E. A. Cockayne [1] there have been numerous outbreaks in the British Isles, and although hardly anything has been added to the symptomatology which he described, the ætiology seems almost more perplexing than it was 16 years ago. There can be no doubt that extensive epidemics of jaundice occur from time to time; the disease is usually limited to children, but when it spreads through a household—as it often does—the adults also are attacked. In the Surrey epidemic of 1927, reported by W. G. Booth,[2] all but one of 107 cases investigated were in children under 15 years of age, whilst in the Midland epidemic of 1925 Morgan and Brown [3] recorded that out of

100 patients 14 were adults—8 of them, curiously enough, belonging to a village where there were only 9 cases in all. We are here dealing with a disease, almost confined to children, which is clinically differentiated from Weil's disease (spirochætal jaundice) only by its comparatively mild course. In the Midland epidemic most of the cases were slight, but all degrees of severity were met with, from death in one case, severe illness in two others, down to a slight constitutional disturbance, accompanied by almost imperceptible jaundice, which would probably have been overlooked if it had not been preceded by graver signs in other members of the same family.

Although, however, Weil's disease and epidemic jaundice present much the same symptomatology, a distinct difference is noticeable in their infectivity. In outbreaks of epidemic jaundice it is not unusual to see as many as three or four children in one family infected, one after another, which is suggestive of a case-to-case infection, whereas in the war epidemic of Weil's disease in Flanders, no case of ward or laboratory infection was observed by Stokes, Ryle, and Tytler.[4] This raises the question whether epidemic jaundice in children is caused by the same organism, *Leptospira icterohæmorrhagiæ*, as is responsible for Weil's disease—a question which has naturally been investigated by many workers. Weil's disease is known to occur in the British Isles from time to time. Manson-Bahr, Wenyon, and Brown [5] in 1922 recorded the case of a seaman who apparently became infected from falling into the Thames and swallowing considerable quantities of water; in this case the leptospira was isolated and there is no doubt that it was the causal organism of the disease. Subsequently Gulland and Buchanan [6] described an interesting outbreak of spirochætal jaundice among miners in East Lothian, and later Lyon and Buchanan [7] gave an account of an outbreak in two families in Edinburgh in 1924, this being very similar to one reported by Hindle and Brown.[8] We thus have records of several outbreaks of infectious jaundice in the British Isles in which the leptospiral origin of the disease has been proved, and in contradistinction to these we have accounts of widespread epidemics of a disease indistinguishable from spirochætal jaundice by any hard-and-fast means. The Japanese observers Ido, Hoki, Ito and Wani [9] state that the infection in Weil's disease is transmitted probably from rats to man by means of the urine of rats, directly or indirectly. A. C. Coles [10] at Bournemouth in 1918 discovered that 9 per cent. of the wild rats harboured the leptospira. A. G. R. Foulerton,[11] working with rats in the London area, reported that 4 out of 101 were capable of infecting guinea-pigs, and later A. C. Stevenson [12] found the leptospira in 30 per cent. of 100 rats mainly from the London district. Although this organism in the wild rats has been shown to be serologically indistinguishable from that which is isolated from human cases of Weil's disease, in some outbreaks association with bathing pools and marshy ground seems to be the most important factor in the ætiology. That the leptospira was not discovered in the epidemics in Surrey and the Midlands is by no means sufficient justification for exonerating this organism. C. C. Okell,[13] as a result of his considerable experience with infected laboratory animals, draws attention not only to the fact that the disease may assume mild and atypical forms, but also to the great difficulty of isolating the leptospira in well-marked cases. This is in accordance with the findings of G. Buchanan [7] who only succeeded in infecting one animal out of 44 from fresh material from the patients in the Edinburgh epidemic, and quotes Inada as only having found leptospira in the blood on two occasions out of 100 cases. It is true that in the Surrey epidemic Okell failed to demonstrate the presence of antibodies in the sera of convalescents; but Garnier and Reilly [14] have found that in mild cases of spirochætal jaundice even 4 c.cm. of serum from a convalescent is insufficient to protect guinea-pigs against the disease.

The ætiology of these mild epidemics of jaundice remains obscure, but there is some evidence that the interval elapsing between one case and another will indicate whether the disease is spirochætal or not. This is by no means always as easy as it might seem, for if there is a single source of infection—e.g., a child during convalescence playing with any friends—it is unlikely that all the cases will be infected simultaneously and therefore show signs of the disease on the same day. What is more probable is that one child will develop it a few days after another, and if this happens, and the causal organism is still undetermined, the impression is given that rapid case-to-case infection is taking place in a family. Discussing this point, Buchanan [15] says that "In outbreaks of jaundice amongst school-children or in families, where case-to-case infection rapidly occurs, spirochætal jaundice can be ruled out"; but care is necessary in applying this rule. In the Edinburgh outbreak [7] there was in one family an interval of 21 days between the first and second cases, then four days between the second and third, and another four days between the third and fourth case, which was strongly suggestive of rapid case-to-case infection, but the disease was nevertheless traced to the leptospira. Future research will, we hope, include further investigation of the serology of the disease with a view to determining the presence or absence of the organism. The suggestions of Buchanan [15] and E. A. Ross [16] that complete bacteriological examinations of the nasopharynx and intestinal excreta should be performed may throw additional light on the ætiology, whilst a more complete study of the blood picture from day to day may be advisable, more especially as regards the differential count. Not only Buchanan [17] with guinea-pigs in the British Isles, but also V. N. Deuskar [18] with human cases in the Andamans, has drawn attention to the very distinctive lymphocytosis present in jaundice which is spirochætal in origin.

THE TREATMENT OF HÆMOPTYSIS.

HÆMOPTYSIS may serve a useful purpose in frightening a tuberculous patient into seeking medical advice. Though there is a fairly large group of cases in which a sudden attack is not associated with any definite physical signs or subsequent ill-health, the symptom is one that demands grave consideration as well as skilful treatment. Fortunately the profession is now alive to the necessity of searching elaborately for the cause in every case, but there is still some doubt about the best method of dealing with the emergency itself. Hæmorrhage from the lungs is more difficult to arrest than bleeding in most other parts of the body, because the bleeding point is not accessible, and also because the lungs are never at rest. When the subject was discussed at the last

conference of the Tuberculosis Association at Oxford, Dr. Clive Riviere [1] pointed out in an opening paper that, owing to natural chemical and physiological processes, the bleeding often tends to stop of its own accord, either independently or in spite of therapeutic endeavours. Rational treatment has, he said, three objectives: to close the bleeding vessel, either by reflex action or by collapse of the lung; to reduce the flow of blood through the pulmonary circulation, by retarding the systemic circulation; and to increase the coagulating power of the blood, by such means as the intravenous injection of hypertonic salt solution, the intramuscular injection of calcium chloride, or the transfusion of serum or of whole blood. He maintained that retardation of the pulmonary blood flow was of more importance than the reduction of the blood pressure in the pulmonary circulation, and he submitted that there was no very satisfactory evidence that the vaso-constrictors, such as pituitrin, or the vaso-dilators, such as amyl nitrite, were useful to arrest the hæmorrhage.

Dr. Hugh Carleton,[2] in another timely review of the subject, says that in pulmonary tuberculosis four types of hæmorrhage may be distinguished. These are the initial hæmoptysis, rarely exceeding one or two drachms; hæmorrhage from a blood-vessel in a cavity directly communicating with the bronchial tree; hæmorrhage due to secondary infection of a tuberculous lesion by septic organisms, which is serious because it tends to recur every few days, the bleeding vessel not being accessible; and, lastly, bleeding from a pulmonary aneurysm, which rapidly causes death from loss of blood or from asphyxia. He believes that it is not the coughing, but rather the exaggerated inspiratory effort following a cough, which is chiefly responsible for the hæmorrhage; during the expulsive stage of a cough the intrapulmonary pressure increases to between 50 and 80 mm. of mercury, and the effect of this increase is to close the capillaries round the air cells and inhibit the flow of blood through the lungs. It follows from this that the actual cough in hæmoptysis is useful, because it expels the extravasated blood, and in order to prevent further hæmorrhage the patient should be encouraged to restrain the depth of the forced inspiration which follows the cough. Nearly all authorities are at one with Dr. Carleton in regarding artificial pneumothorax as the most valuable method of arresting tuberculous hæmoptysis which cannot be controlled by other means and in checking repeated small hæmorrhages. By compressing the lung the blood-supply is diminished, the pulmonary arteries and veins being no longer held open by the negative intrathoracic pressure; the cavities in the lung are compressed, and the tension on vessels spanning the cavities is released; and the risk of aspiration of blood to other parts of the lung is diminished. Lastly, nursing is carried out more easily and the patient may be placed on a full diet. A less efficient, but quite useful, method of prevention is to strap the affected side of the chest. As regards drugs, he thinks morphia useful to allay the distress of an unproductive cough, and to ease the pain of pleurisy, but not to stop pulmonary hæmorrhage. In this, again, he is in agreement with current opinion. A cynic has said that the proper way to use morphia in hæmoptysis is to give it to the patient's relatives and friends, and it is now taught that morphia is dangerous when given during the attack, on account of the abolition of the cough reflex, and the consequent danger of aspiration broncho-pneumonia. This attitude towards the drug has probably arisen from its abuse or excessive use. A small injection (gr. 1/6) at the onset does not abolish the cough reflex, and is certainly of value in calming an excitable and terrified person, as well as fulfilling one of Dr. Riviere's objectives—namely, that of slowing the rate of the heart-beat and of lessening the blood-flow through the pulmonary circulation. The danger of morphia in hæmoptysis arises when repeated injections of large doses are given and the cough reflex is actually abolished. It is remarkable how very few cases of aspiration pneumonia arise when the drug is judiciously used. The necessity for reassuring and calming the patient is probably not enough stressed at the present time.

The bronchial artery is more widely distributed to the lung than is generally recognised. If the bronchial arteries of a pig are injected with barium, it is seen that the main branches follow the bronchi closely, whilst cross sections show that the larger branches are situated in the peribronchial spaces, and only the smallest filaments are sparsely supplied to the submucous tissue of the bronchial mucous membrane. This meagre distribution of very small vessels under the mucous membrane, in Dr. Carleton's opinion, explains the rarity of severe hæmoptysis in chronic bronchitis.

Annotations.

"Ne quid nimis."

SOME HOSPITAL PROBLEMS.

THE British Hospitals Association, which is at present, in effect, our only bureau of information upon all subjects connected with the voluntary hospitals, has just held its annual conference at Southport. The two days' sittings were inevitably overshadowed by the death, a few days previously, of Lord Hambleden, the honorary treasurer of the Association, which has owed much for years past to his sympathy and counsel. The conference was, however, well attended, and papers were read and discussed upon subjects and problems which are daily before the eyes of hospital administrators. The principal paper, however, that read by Sir Thomas Horder on the Place of the Voluntary Hospitals in relation to Health Services, dealt with a matter which touches the whole community, and has implications of the first importance in relation to the public health. So much has been said about it of late, both by supporters and critics at the voluntary hospitals, and by the candid friends who are both, that it is difficult to enunciate anything fresh. We may note, however, that Sir Thomas Horder lends his support to the widely accepted view that "a large number of beds in the poor-law infirmaries should be more efficiently utilised and should receive more definite and systematic medical supervision." One of the objects of the coming revision of the poor-law should be the better use of some of the infirmary beds in close association with the voluntary hospitals. We have to be careful not to overdo all that is connoted by that blessed word "coördination," but some form of coöperation has become as inevitable as it is essential, and the form it is to take will need to be worked out very carefully, not by a Ministerial department working on interior lines, but in close consultation with authorities of the highest practical experience.

Sir Thomas Horder thinks that the fears of the voluntary system coming under State control are a bogy, and he is probably right. It would be a very foolish and a very extravagant State which determined to obtain such control, but States are often foolish and, still more often, extravagant. Happily the voluntary system is emerging successfully from tests which might well have broken it down, tests which it is unlikely to have to face again for a long time. Yet the pressure upon it grows, not gradually, but rapidly, and failing coöperation between it and the municipal system much money and effort will be wasted and, what would be infinitely worse, much that lies at the root of improvement in the national health would be imperilled. It is only by this coöperation that it will be possible to obtain, among other desirable

things, that linking of consultant services on a really wide orbit, the need for which was urged by Mr. H. L. Eason. The Council of the Association, in its report to the conference, once more expressed its readiness to coöperate in a reasonable scheme of reform, an assurance the value and significance of which should not be underrated in view of the representative character of the organisation.

It is a little surprising that the Council should be of opinion that it is chiefly the smaller hospitals in outlying districts that are concerned with the uncomfortable consequences of filling their beds with motor casualties. To many of the large hospitals in great centres these casualties have become a nightmare, though it is obvious that a single bad accident may heavily overtax not for days but weeks a small institution which has no reserve of accommodation. As was to be expected the Council favour the suggestion of the Voluntary Hospitals Commission that, as a way of relieving hospital difficulties of this kind, motor insurance should be compulsory. One of the most interesting of the Southport discussions arose upon the paper on the Place of the Nurse in the Hospital, read by Miss M. E. Sparsholt, the experienced lady-superintendent of nurses at the Manchester Royal Infirmary. Not many years ago Miss Sparsholt's list of "necessities for nurses" in the way of comfort, convenience, and recreation would have seemed formidable, but the nurse of to-day is a much more highly trained person than her predecessor of yesterday, and her work is much more responsible. It is no longer enough that she should just obey the doctor—she has it in her power, very often, materially, to help him and the patient whose every variation she is able to watch. There are already difficulties about obtaining the right type of young woman for this often difficult and always laborious work, and one of the best ways of meeting those difficulties is to enable the student nurse, when she is not on duty, to follow the same pursuits as are enjoyed by girls who have chosen a less exacting career. She may prefer to spend some of her scanty hours of leisure within the walls of the hospital, and it is highly desirable that she should find there the amenities of a comfortable home.

THE CAMPAIGN AGAINST VENEREAL DISEASE.

In connexion with the recent meeting convened by the International Union Against Venereal Disease at Nancy, an arrangement was made between this body and the League of Red Cross Societies, according to which the latter's journal, the *World's Health*, should devote its June number to venereal disease. The enterprise shown in this matter by the Union's new secretary-general, Dr. Cavaillon, is most promising. In the first paper of this special number Prof. Bayet, chairman of the Union, outlines its aims. They are, as they should be, very ambitious. With regard to international coördination, he draws attention to the present lack of unanimity throughout the world as to the best methods of combating syphilis. Some countries concentrate on preventive and social work, some on disinfection of infected persons, some on laws and regulations, and some do what they can here and there without any unified plan. Prof. Bayet hopes that, by full discussion of the merits of the respective methods, the most effective may not only be recognised, but also adopted, in every country. While the Union disclaims any desire to impose a rigid system of prevention and treatment everywhere, it hopes to find and give prominence to certain general principles based on scientific research, and to leave the application of these principles to the special needs of each country. Dr. Cavaillon follows up this general outline with a more detailed account of what the Union is and hopes to do. It numbers 55 organisations working in 35 different countries, and it hopes to obtain supervision of emigration and inspection at the frontiers in connexion with venereal disease. Another aim is to get the international agreement regarding merchant seamen signed and applied everywhere. It also has a policy with regard to prostitution, and it aims at conducting a universal propaganda campaign which is, perhaps, the most important of all its objects. In this special number of the *World's Health* there are separate papers on the work of the League of Red Cross Societies, the League of Nations, the International Labour Office, and on the campaigns undertaken against venereal disease in each of the following countries: Austria, Belgium, Brazil, Bulgaria, Canada, Czecho-Slovakia, Esthonia, France, Germany, Great Britain, Greece, Hungary, Italy, Japan, Luxemburg, Netherlands, Spain, Switzerland, and the United States of America. Anyone interested enough in the subject to read this special number from cover to cover must agree with Prof. Bayet in his remarks on the diversity of methods employed in the different countries. By putting the accounts of these methods side by side the Union has given an effective demonstration of its policy of international comparison and unification.

INTERLOBAR EMPYEMA AND ABSCESS OF THE LUNG.

It is important to distinguish between abscess of the lung and empyema, because both treatment and prognosis are different. For this reason the possibility of interlobar empyema should be kept in mind, especially as a complication of pneumonia. G. Dieulafoy, whose brilliant account of the condition of 1900 has become classical, described two modes of onset; first and most commonly as a post-pneumonic or para-pneumonic complication, and, secondly, as an insidious sequel to indefinite pulmonary congestions. Basing his classification on the symptoms and anatomical lesions, he divided the course of the condition into stages—namely, the closed stage, in which the patient has constitutional signs and symptoms of suppuration, but no special respiratory symptoms; and later the open stage, when the empyema has burst into the lung, with attendant intermittent expectoration of pus, hæmoptysis, and foul odour of the breath. He further emphasised the "suspended" nature of the physical signs—i.e., the presence of an area of dullness in the middle region of one or other hemithorax with comparatively normal physical signs above and below the area.

Dr. Raoul Kourilsky shows [1] that it is very difficult—indeed, almost impossible—to distinguish on clinical and radiological evidence the open stage of interlobar empyema from pulmonary abscess occurring in the region of the interlobar fissures. He points out that, since Dieulafoy's paper was published, the general tendency in France and elsewhere has been to diagnose interlobar empyema on insufficient evidence, without controlling the diagnosis surgically or post mortem. The general attitude of medical opinion towards interlobar empyema may be stated thus: when in a patient with intermittent purulent expectoration, hæmoptysis and fever, an area of "suspended" increased density is observed clinically, and when this is confirmed radiologically by the presence of a transverse shadow suggesting air and fluid, surrounded by broad shadows indicating increased density and congestion of the lung at the level of an interlobar space, a diagnosis of interlobar empyema is made. When, in a patient who expectorates pus, and who is not tuberculous, the existence of a focus with or without cavitation is established and shown to be situated in a lobe of the lung, but not in relation to an interlobar fissure, a diagnosis of abscess of the lung is made. Kourilsky points out that the diagnosis of interlobar empyema is generally wrong, and that nearly always the condition turns out to be a pulmonary abscess. Of 52 cases of intra-

[1] Kourilsky, Raoul: Abcès du Poumon et Pleurésies Interlobaires, Arch. Med. Chir. de l'Appar. Resp., 1927, ii., 297.

thoracic suppuration, 14 were diagnosed as interlobar empyema, nine of these at operation or autopsy proving to be abscess of the lung in the region of pulmonary fissures. Of the remaining five only two were shown at operation to be interlobar empyema, whereas the diagnosis in the other three cases, even after operation, was not definitely established. Kourilsky thinks that it is possible to make an exact diagnosis at operation only in cases where the abscess cavity can be investigated thoroughly by manual examination and the lung is felt to be elastic and not consolidated. He further maintains that only at autopsy can a positive diagnosis be made. It is interesting that none of the 14 cases in which interlobar empyema was diagnosed arose as a complication of pneumonia, and that in the two cases in which he was satisfied that the diagnosis was correct the condition was post-operative.

The conclusions Kourilsky reaches are that interlobar empyema is actually very rare, and that abscess of the lung is usually the correct diagnosis when the symptoms are those of Dieulafoy's open stage of interlobar empyema; that the diagnosis of interlobar empyema is possibly more plausible when the symptoms arise as a post-pneumonic complication and not insidiously; and that it is extremely important to differentiate between the two conditions because the treatment varies in each case. In surgical interference for abscess of the lung it is essential, if pleural adhesions have not already formed, to suture the parietal and visceral layers of the pleura before opening the abscess, whereas in interlobar empyema incision and drainage usually lead to cure. The prognosis of interlobar empyema is much better than that of abscess of the lung. According to J. Comby and others, interlobar empyema is more common in children than in adults, whereas pulmonary abscess is often encountered in adults, but very rarely in children. Study of the radiograms and clinical reports in Kourilsky's series suggests that most of the erroneous diagnoses arose from misinterpretation of the radiological appearances. Apparently there is a tendency in France to ascribe a shadow indicating air and fluid (*image hydroaérique*), especially if the long axis is transverse, to the presence of interlobar empyema. After pus has been withdrawn on exploratory puncture, an *image hydroaérique* means pyopneumothorax. The causes of this condition are numerous, and an interlobar empyema rupturing into a bronchus is one of the rarest of them.

THE TALE OF MEDICAL RESEARCH.

AT the annual meeting of the Research Defence Society held recently in London, Sir Bernard Spilsbury delivered the second Stephen Paget Memorial Lecture on the "Work and Responsibilities of the Pathologist," and his address will be found in another column of this issue. It is a model of what a public deliverance should be, when the intention is to reveal to the layman not only the results of medical science, but the basis of the work done, so that the reasons for various procedures may be realised and, incidentally, so that the completely foolish nature of much criticism may be revealed. Intelligent citizens can detect from Sir Bernard Spilsbury's deliberately simple explanations the groundwork of much modern pathology, while medical practitioners, who may find themselves asked to refute heresies promptly, need not go beyond his words for the needful arguments. That vigilance of this sort is required on the part of the medical profession, in order to protect the public from ill-placed sentimentality, was made clear by Lord Knutsford, who, following Sir Bernard Spilsbury and proposing the vote of thanks to the lecturer, read to the meeting a post card which had been sent out from the British Union for the Abolition of Vivisection. The post-card was an invitation to the members of the Union to write to the British Broadcasting Company, and to suggest that Dr. Hadwen should broadcast a talk upon vivisection, while the recipients of the post card were requested not to send that document itself to the B.B.C., inasmuch as their communications would "have more influence if the B.U.A.V. is not mentioned." Sympathy with the kind-heartedness of those who oppose medical research is likely to be blunted by procedures of this sort, as it will also be alienated by their resolute blindness to evidence. At the business meeting of the Research Defence Society, presided over by Lord Lamington, Mr. F. J. Peart publicly recanted his signature to a declaration which he had given as a member of the staff of the Battersea (Antivivisection) Hospital not to countenance experiments on animals unless they were designed for the benefit of animals. His action arose from finding that he was unable to treat a case of tetanus in the wards of the hospital with antitetanic serum, and was consequently obliged, in the interests of the patient, to treat the patient surreptitiously. It is certain that if the authorities of the Battersea Hospital had learned the lessons, old and oft-repeated but excellently summarised, in Sir Bernard Spilsbury's Memorial Lecture, they would have hastened to permit Mr. Peart, in the cause of humanity, to carry out scientific treatment.

REMOVAL OF THE RIGHT CEREBRAL HEMISPHERE IN MAN.

THE progress of surgery has been marked by increasingly bold removal of structures that were previously regarded as essential to the life or well-being of man. With the development of antiseptic surgery the abdominal cavity has most readily lent itself to these onslaughts, and it has become a matter of history that man can exist in comfort without his spleen, gall-bladder, and large portions of his gastro-intestinal tract. In other parts of the body progress has not been so easy, and interest is now centred on what surgeons may be able to accomplish within the thorax and cranium, regions which have been aptly called the Great North-west of Surgery. The latest feat of exploration in these regions is the removal of the right cerebral hemisphere, reported by Walter E. Dandy.[1] In five cases of extensive deeply seated glioma Dandy has completely removed the right cerebral hemisphere. One patient died from hæmorrhage within 48 hours, another died two weeks after operation from pneumonia, a third and fourth died of recurrence, one three months, the other 3½ years after operation, while the fifth patient was still alive, two months after operation, at the time of Dandy's report. The patient who lived for 3½ years after operation was originally admitted to hospital in coma and proved to have an extensive glioma of the right frontal and temporal lobes. The result in this case may therefore be considered remarkable. The operation is, of course, followed by left homonymous hemianopsia and by permanent paralysis and anæsthesia of the left side of the body, but, as would be expected from past experience of excision of various portions of the right cerebral hemisphere, it does not produce any obvious mental impairment. Dandy finds that the paralysis is complete in the left leg and arm, but only partial in the left side of the face. Rigidity develops very slowly in the paralysed limbs and is never pronounced in the leg. Deep sensation is well preserved and movements of the paralysed limbs are sometimes painful. Hearing remains normal in both ears, a finding which disposes of the assumption that there is cortical representation for hearing in the right temporal lobe. Dandy's paper thus contains important physiological observations, and it is to be regretted that his cases are not reported in detail. From the practical standpoint it is doubtful whether the operation of complete removal of the right cerebral hemisphere will ever become popular with neurological surgeons or their patients. Retention of life at the

[1] Jour. Amer. Med. Assoc., 1928, xc., 823.

cost of permanent and perhaps painful hemiplegia is a prospect that will not commend itself to many patients, even though they are already paralysed when they seek treatment. The hemiplegia produced by an invasive tumour of the hemisphere is probably more often due to pressure on the pyramidal tract than to actual destruction of its fibres, and it therefore seems likely that some form of radiation will ultimately provide the best means of attacking deeply seated gliomas.

JAUNDICE DUE TO MOVABLE KIDNEY.

IT has for long been known that jaundice may sometimes accompany movable kidney, but the exact relationship between the two conditions has been a matter of dispute. The kidney is intimately in contact with the duodenum, and if in the course of its descent it acts as a drag on this organ, jaundice may actually be due to mechanical obstruction of the common bile-duct. A. J. Schole [1] reports a case history which is of interest in this connexion. A man sustained an injury to the back which necessitated an operation to suture the lacerated and displaced kidney and to restore it to its proper position. He remained well for over 20 years, when another injury caused an attack of pain and jaundice and, in fact, initiated a train of symptoms referable to the gall-bladder. These symptoms had already continued for 18 months when the patient came under observation. At its height the jaundice was so intense that no bile at all flowed into the intestine. A radiogram revealed a collection of stones in the right lumbar area. These, together with the pyuria, led to a renal investigation, when a right pyonephrosis was found to be present. After drainage of this lesion through a ureteric catheter the jaundice disappeared, but it returned immediately the catheter was removed; the catheter was replaced and again removed, with the result that the jaundice again disappeared and returned. Nephrectomy permanently cured the gall-bladder symptoms. Dr. Schole believes that drainage of the pyonephrosis allowed subsidence of the perirenal infection and thus diminished the pressure upon the common bile-duct. In the literature on the subject there are to be found a certain number of cases where fixation of a dropped kidney has cured attacks of jaundice, but the association is curiously rare considering the anatomical relations of the kidney to the duodenum close to the entrance of the common bile-duct. This may be due to the fact that unless an infection of the movable kidney takes place, leading to some perinephritis, the organ slips rather easily up and down behind the perineum without exerting any pull upon the duodenum itself.

THE ROYAL COLLEGE OF SURGEONS MUSEUM.

IN his annual report on the museum of the Royal College of Surgeons of England the Conservator refers to the continued increase in the size of the collection and the problem of providing space for its accommodation. He anticipates, as a possible necessity, some limitation in the scope of the museum, since enlargement of the building is precluded owing to the limited financial resources of the College. A similar measure was resorted to on the foundation of the Natural History Museum, South Kensington, when the subjects of zoology and comparative anatomy were excluded from the aims of the College museum. The report of the curator, Mr. Cecil Beadles, on the present pathological collection gives evidence of a strenuous year's work; in addition to the work of recataloguing the collection of special pathology, which appears to have made fair progress, no less than 850 specimens, including the additions, have been remounted during the year. Of the new specimens, 150 in number, the curator refers to many of great interest, among which may be mentioned a fine series from a case of Recklinghausen's disease showing widespread involvement of the cranial, spinal, and sympathetic nerves; and a tibia from a second case showing the rare involvement of the periosteum in the hyperplastic process, with associated deformity of the bone. Other specimens of interest are a femoral aneurysm of tuberculous origin, a chondroma of the lung arising from the bronchial cartilages, and a lymphadenomatous enlargement of the thymus gland forming a tumour some six inches in diameter, which was removed by operation from the anterior mediastinum. Mention should also be made of a series of specimens from cases of pernicious anæmia; these were presented by Dr. William Hunter and illustrate the changes in the tongue, stomach, and intestines which, as is well known, he regards as characteristic of the disease. In the physiological department very interesting specimens are added by its curator, Mr. R. H. Burne, F.R.S., showing injections of the afferent vessels of the lymphatic circulation in fishes, the discovery of which throws light on the nature and evolution of the lymphatic system generally. The additions to the museum will be on view in Room 1 from July 5th, the date of election of new members to the Council, until July 28th. A passing reference merely can be made to the active work in progress in the osteological, odontological, and historical sections, detailed accounts of which have appeared in previous reports. A valuable series of casts illustrating the surgical methods of treatment of cleft palate have been presented by Sir James Berry through Sir Frank Colyer, and the museum now possesses an exact cast of the Taungs skull, the gift of Prof. R. A. Dart. A task of some magnitude has devolved on the museum in connexion with the Strangeways collection of specimens of chronic arthritis, several hundreds of which have been accepted from the trustees of the collection. Dr. Strangeways never published the results of his investigations and his manuscripts and specimens have now been placed at the disposal of Mr. Lawford Knaggs, who has undertaken their examination and revision. A kindly reference is made in the report to the serious loss sustained by the museum in the death of Mr. Alban Doran; his erudition and scholarship were devoted to the museum during many years, and they have a lasting memorial in the descriptive catalogue of the Collection of Surgical Instruments, a work of a kind that very few have the learning and ability to undertake.

THE ACNE OF ADOLESCENCE.

FACED with a stubborn case of acne it is not enough to encourage a hope that the affliction will have passed by the end of the patient's third decade of life. The anticipation is not always fulfilled, and in the meantime the victim of this complaint is suffering under a disability that may prove a serious handicap. Considered in the light of its effect on careers and self-confidence, acne is often far from trivial, and every case demands a serious attempt to use the means of cure at our disposal. These were ably summarised not long ago by Dr. D. E. H. Cleveland.[1] He does not pin his faith to this or that particular remedy, for the very good reason that there is no one cause for the condition to be treated. The ætiological components include both physiological and morbid tendencies, not forgetting an inherited predisposition of the skin, which may be either greasy (seborrhœic) or dry. Though the presence of septic foci in teeth and tonsils, constipation or chlorosis are doubtless aggravating factors they are in no case causal, and very few cures can be registered by their elimination alone. These and many other subjects, such as exercise, diet, habits, and fresh air, are rationally considered by Dr. Cleveland, who passes on to discuss in their relative importance the various methods of treatment available. He condemns the use of cosmetic creams and excess of tobacco, carbohydrates, and cooked fats. He does not favour hot baths

[1] Trans. Amer. Assoc. Genito-urinary Surgeons, 1927, xx., 223.

[1] Canad. Med. Assoc. Jour., 1928, xviii., 261.

mless they are followed by a cold shower, and ecommends that the patient should be made to hampoo the scalp every week. After a short list f simple and well-tried local applications recomnended by Darier, Sabouraud, Duhring, and Ormsby, ie concludes by devoting only a small space to the ndications for ultra-violet and X ray treatment. n this respect he will have the support and comnendation of most expert opinion. There is far too nuch resort to methods based on the fashion of the noment, and patients will often demand a particular :ind of treatment because it was used with success n the case of a friend, or because they have read bout it in the lay press. It is interesting to compare he reserved statements on treatment with X rays n this paper with those made by Dr. J. L. Webb.[2] The latter evidently has no qualms and appears to se the method in every case after removal of each ndividual comedone, the incision of pustules, and ntradermal use of a vaccine. Whilst mentioning he cost of the treatment he makes no mention of ts dangers, and if, as is stated, "three-quarters of n erythema dose, *unfiltered*, are given each week," here is reason to fear that these are not very remote. Dermatologists agree that X rays are a valuable djunct to treatment in severe and intractable acne, ut most of them would condemn its use as a routine, ot only because it may do permanent damage to ndividuals, but because one or two disasters would ring the method into disrepute. Assertions like hose made in this paper are not infrequently followed iterally by persons whose knowledge of the subject as been gained solely from text-books or by a short ttendance at some clinic. Few of them have had a horough training or an opportunity of seeing the ppalling late results of X ray burns of the face—harvest which we are now beginning to reap rom the earlier treatment of lupus vulgaris and ypertrichosis.

INFECTIOUS DISEASE IN SCHOOLS.

FORTY-FOUR years ago, when the Medical Officers f Schools Association was founded, questions were ent to every important school in this country to scertain what precautions were taken to guard gainst infectious diseases. At this time many of he leading institutions maintained a policy of ecrecy about the health and sickness of their pupils, fact which had hindered THE LANCET Sanitary ommission on Public Schools in its inquiry a few ears before. The attitude of others was typified y the proud advertisement that no doctor had isited them for several years, and it was not surprising hat the Association's questionaire revealed differnces in theory as well as laxity in practice. The esult was that the Association issued a Code of Rules[3] for the Prevention of Communicable Diseases n Schools, which, in its numerous editions, has roved of great value not only to school authorities ut also to parents and guardians. At the time of its ppearance we commended these rules as practical nd plain, and the same words apply to the ninth dition which has just been published. It contains, s before, chapters on general hygiene, the infirmary, he medical examination of scholars, general preautions against the introduction and spread of isease, and measures to be adopted when infections ave broken out; but its usefulness has been greatly xtended not only by expansion of these sections but y the addition of a "definition of terms" based n data published by the American Public Health ssociation in 1926. This includes a list of the ommoner infections, with brief notes on the infectious gent, the source of infection, the mode of transission, the incubation period, the period of comunicability, the methods of control, and the time f return to school. It forms a concise and dogmatic tatement of our knowledge of infectious disease from the point of view of schools, and it will be acceptable to every practitioner who wishes to have the facts available for ready reference. Two short appendices describe the modern methods of preventing diphtheria and scarlet fever, and the treatment of tinea, whilst a third, also new, briefly discusses the policy of excluding infection from schools, in the light of recent work on "herd immunity." Another appendix summarises the general theory of disinfection, little understood outside the profession.

THE WATER OF THE METROPOLIS.

THE result of chemical and bacteriological examinations of the London waters covering the year ending Jan. 1st, 1928, has just been issued in the form of Sir Alexander Houston's twenty-second annual report as Director of Water Examination to the Metropolitan Water Board. The report contains interesting accounts of the chlorination of Thames and New River water, of which we have now 12 years' experience, an experience so satisfactory as to have led to the discontinuance of protests on the ground of doping. Evidence is here set out to show that this treatment of potable waters not only provides a valuable measure of security, but has the great financial advantage of producing a better water than can be achieved by prolonged storage, although for other considerations additional storage accommodation in the London areas may be necessary. Neither the Thames nor the Lee, which, excluding the Kentish wells, form the main source of the water-supply of "Water London," can be considered ideal for the purpose which they serve, but though the prefiltration fluid may be considered unsatisfactory compared to a virgin mountain stream, yet the waters, as judged by the *B. coli* test, can be, and are, improved from 100 to 1000 times by judicious and unceasing treatment. This is certainly a matter for satisfaction, but improvement in quality consequent on storage should not be used as an argument for relaxation in purification, as this report shows.

Among the varied contents of a long and closely packed document[1] some interesting notes on the meteorological circumstances of the year show how a period of persistent wet affects the water-supply of an immense urban community. We are thus reminded that last year February was dreadfully wet; that March and April were wet; that, though May was a rather dry month, June, July, and August were wet and cold; and that September and December were exceptionally wet months. In November the rainfall was about normal, and in October alone it was really below normal. These circumstances formed a trying year for all responsible for waterworks. First, the water-supply was brown in colour over long periods, and it was hard for consumers not to eye it with suspicion. Further, water may actually deteriorate in quality during floods if accompanied by seriously cold weather, as frost interferes with the filtration processes. And this occurs exactly when the rate of filtration has to be increased to meet an augmented demand for water, arising to an appreciable extent from the wily extravagance of householders, who leave taps running in order to protect themselves against the bursting pipes.

Last year it may be remembered that, as a preliminary to the scientific description of the water-supply of London and the chemical and bacteriological tables reinforcing the information, Sir Alexander Houston described the Kent wells, and in so doing suggested that water-supplies should not be divorced from their historical settings or associations. This idea is again present in the twenty-second annual report, wherein the river Lee is described at length as a source of water-supply in an elaborate essay illustrating, by pen and photograph, the whole course of the river. The beauties of the stream as

[1] Metropolitan Water Board: Twenty-second Annual Report. London: P. S. King and Co., Ltd. Pp. 102. Profusely illustrated. £1 1*s*.

it passes through the lovely Hertfordshire scenery are eloquently set out, with ample literary references, and its tributaries receive similar notice. We congratulate Sir Alexander Houston on his successful blend of science and letters.

QUALIFIED PRACTICE IN PHYSICAL TREATMENT.

THE advantages to be derived from physical treatment are becoming better known not only to the medical profession but to their patients. To give only one example, the public are nowadays prepared to pay a reasonable price for massage after fractures and are likely to demand prescription of this treatment if it is not spontaneously suggested to them. Unfortunately, a large number of unqualified people, by specious advertisement and otherwise, are attracting to themselves much of this work, to the disadvantage of the patient and to the cause of physical treatment generally. The publication of the recent Register of Members of the Chartered Society of Massage and Medical Gymnastics [1] shows that there are now 6570 men and women who are qualified, by training and examination, to carry out physical treatment. It will be seen from the place index which forms part of the Register that there are few, if any, districts where none of its members is available. It is easy to distinguish between the qualified and unqualified, since under the Charter members of this Society alone are entitled to style themselves "Chartered Masseurs" and "Chartered Masseuses." Before registration each candidate for membership has to sign an undertaking not to treat any case except under the direction of a registered medical practitioner; not to advertise except in recognised medical and nursing papers; not to sell goods to patients in a professional capacity, and not to accept secret commissions on the sale of goods. It is seldom that these undertakings are not faithfully respected, and it would seem only fair that members of an ancillary profession which is so loyal to medical practitioners, should receive corresponding support. There is good reason to believe that this is not always forthcoming, possibly because the activities of the Society are not sufficiently well known, though attention has frequently been drawn to them in these columns.

One of the duties of this Society is to inspect all the schools in which candidates for the Society's examinations are being trained. This inspection is carried out in the most searching manner, and every attempt is being made to bring those schools which lag behind up to a proper state of efficiency. The progress made since the Charter was granted in 1920 is remarkable, and if the Society receives the support which it deserves, the standard of physical treatment in this country should reach a high level.

HYDROCYANIC ACID AS AN INSECTICIDE AND RATICIDE.

Hydrocyanic acid is much used as a means of killing rats, bugs, and other vermin, more especially on ships. About its efficacy there can be little difference of opinion, but it is very poisonous, and elaborate precautions have to be taken to ensure the safety of human beings and domestic animals exposed to risk. It appears that in France this deadly substance has been used for "disinfecting" houses, and as accidents have been reported the Paris police have now forbidden its employment in any form for disinfection or for the destruction of harmful animals in habitations. It certainly seems undesirable that this or any other poison gas should be used in any place which cannot, like a ship, be effectively isolated from surrounding dwellings. Such isolation is impossible in any house which is not detached from other buildings and distant from public highways. Detached houses standing in their own grounds are not usually overrun with bugs, but cockroaches only too often abound in old country houses which have been fitted with central heating. Those who are tempted to use so efficacious a means of killing these vermin should remember the Paris edict. Information about the way the gas is used will be found in a pamphlet [1] recently issued by the Ministry of Health. The particulars it gives will enable any ordinarily intelligent person to generate, use, and dispose of the residues left after use of HCN, and it includes valuable information on gas masks and on first aid for persons overcome by the gas.

As was announced last week, subscribers to the Dawson Williams Memorial Fund will meet at the Royal Society of Medicine, 1, Wimpole-street, London, W., on Tuesday, July 10th, at 5.30 P.M., to receive the statement of Sir StClair Thomson, the hon. treasurer, and to decide upon the form of the memorial. The organising committee recommend that the memorial should take the form of a "Prize to be awarded every two years, or at longer intervals, for the best work which has appeared on pediatrics since the previous award." The list of subscribers will remain open until July 10th, and contributors should send their cheques to Sir StClair Thomson before that date. At present the net amount to be invested will be somewhat over £800. The meeting will also be asked to make arrangements as to the trusteeship of the Fund.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXXII.

THE TREATMENT OF ONYCHIA.

THE term "onychia" is usually defined as an inflammation of the matrix of the nail, but in practice it is used rather more loosely to include inflammations of the nail bed and also of the nail folds, though for the latter the term perionychia is often used. It is however often difficult, clinically, to separate inflammations of the nail matrix and bed, and hence the term onychia is often employed to cover inflammations of all these structures.

Inflammations of the nail may result from physical or chemical injury, from local infection by bacteria or fungi, or may be a part of some general inflammatory eruption, such as syphilis, eczema, or psoriasis. With this last group we are not concerned in this article.

Physical injuries to the nail may be traumatic—crushing, bruising, and the like; due to heat or cold—burns and frostbite; or to harmful radiations, as in X ray and radium dermatitis.

Chemical injury to the nails is frequently seen in industrial workers; it is almost invariably secondary to dermatitis of the fingers, but not infrequently this inflammation spreads over the nail folds and involves the matrix, usually producing a chronic type of onychia with mal-growth of the nail, so that this latter becomes rough, thickened, and furrowed. The treatment consists of removing the cause and dealing with the associated dermatitis with soothing and protective applications, the nails requiring no special treatment.

It is, however, to the infective types of onychia that our attention is specially directed; of these there are two groups: pyogenic onychia and mycotic onychia.

Pyogenic Onychia.

Pyogenic onychia is a common affection, and may be due to infection either with streptococci or

[1] Printed for the Society by the Campfield Press, St. Albans. Pp. 266. 4*s*.

[1] Memorandum on the Fumigation of Ships with Hydrogen Cyanide. H.M. Stationery Office. 1928. 1*d*.

staphylococci. The former is not infrequently seen in children in association with impetigo contagiosa, while in adults staphylococcal infection seems more frequent. In adults the infection is more common in women than in men, and this doubtless is due to their more frequent use of manicure instruments and also possibly to the fact that they have their hands constantly in water. Several types are seen, of which the following are the most frequent:—

1. *The Acute Suppurative Type* usually affects a single nail, is associated with much swelling of the nail fold, and frequently involves the matrix, so that the nail is sooner or later shed. The swelling is confined to the nail fold and the tissues immediately surrounding it and does not involve the ball of the finger. There is often a good deal of pain and tenderness localised to this area and to the root of the nail. Pus can be squeezed out from under the nail fold. As the nail separates granulations make their appearance under the root of the nail. In the early stages it is advisable to soak the finger two or three times a day in a 1 in 4000 solution of potassium permanganate and to dress it with 1 in 4000 perchloride of mercury fomentations. Many cases will subside with this treatment alone. In some cases Bier's cupping may also be applied. If there is evidence of involvement of the matrix it is better to remove the nail at once. This is indicated when the pain is not relieved by fomentations or baths, or when pus can be squeezed out by pressure on the base of the nail as distinguished from pressure on the nail fold. Incision of the nail fold is better avoided; it is rarely necessary for drainage and may increase the area of infection.

2. *The Recurrent Suppurative Type.*—In this variety several nails are frequently affected, and the symptoms are less severe, but tend to clear up for a time and then recur. The matrix is not usually much involved, but slight irregularities of the nail growth may occur, indicating slight involvement of this structure. In these cases evulsion of the nail is rarely necessary or even successful, recurrences tending to occur even after several removals. It is most important to protect the nail fold from injury, and a weak antiseptic dressing, such as 1 in 4000 perchloride of mercury, should be worn till the inflammation has subsided; then, for several months, a light cotton finger-stall should be worn as a protection and the hands should be kept out of strong soapy or alkaline solutions. Bier's cupping is also useful in resistant cases. Dr. A. C. Roxburgh [1] has had success with a method suggested by Dr. H. G. Adamson of inserting a small pledget of cotton-wool soaked in pure carbolic acid under the nail fold twice a week. It is in this type of case that an autogenous vaccine may be tried, though the results are not uniformly successful.

3. *Chronic Non-suppurative Type.*—This variety, which usually attacks many fingers and causes much deformity of the nails, can be very successfully treated by X rays. It is essential, however, to give only small doses. One-third of a Sabouraud pastille dose given once a week for four weeks is the maximum that should be given at one time. This usually clears up the condition, but if it does not the treatment should be abandoned. If recurrence takes place, the doses can be repeated after an interval of two months. I have not found X rays of much value in the suppurative cases. If X rays are not available, the nail folds and roots of the nails may be painted twice daily with 1 in 1000 flavine in liquid paraffin and light cotton finger-stalls worn. It is of extreme importance in these cases, as in the last type, to avoid all injury, however slight, to the nails and their surroundings. In all these types of case ointment should be avoided.

4. *Septic Infection of the Nail Bed.*—Occasionally septic infection of the nail-bed occurs, as, for example, when a splinter is pushed in under the free end or lateral margins of the nail. When this happens a small abscess may develop under the nail, and is indicated by the presence of severe pain under the nail and of tenderness usually localised to a relatively small area. After a day or so a small yellowish spot appears, and this increases in size, the symptoms meanwhile becoming intensified. In these cases all that is necessary is to cut away the portion of the nail over the small abscess so as to allow free drainage and to foment with a 1 in 4000 perchloride of mercury dressings.

[1] Clinical Journal, Jan. 27th, 1926, p. 41.

Mycotic Onychia.

Ringworm fungi and favus not infrequently attack the nails and produce a variety of lesions. The organisms of thrush and other monilia may also produce onychia. Infection commonly takes place from the free edge, leading to a gradual separation of the nail from its bed, but it may also commence under the nail fold and at the lateral margins. A certain diagnosis can only be made when the fungus can be demonstrated in scrapings. The condition is difficult to treat, and it is usually necessary to remove the nail. This can be done either by evulsion or by softening the nail with liquor potassæ, carefully applied to the nail surface and scraping the softened nail away gradually. When this is done dressings of Whitfield's ointment (5 per cent. benzoic acid and 3 per cent. salicylic acid) should be applied. Norman Walker's method is very efficient; it consists in applying Fehling's solution on a piece of lint cut accurately to fit the nail, after having applied an ointment to the surrounding skin. A rubber finger-stall is then fitted and left in position for 12–24 hours. When it is removed, the nail can be scraped away and a mild antiseptic ointment applied, or weak mercurial fomentations if there is much inflammatory reaction. Thereafter, iodine ointment, or Whitfield's ointment, can be used till the nail regrows.

If only the distal portion of the nail bed is involved it may suffice to cut away only that portion of the nail which overlies the affected area, and then instil two or three times daily tincture of iodine or 1 in 1000 perchloride of mercury in 90 per cent. alcohol.

G. M. McKee has used X rays with some success in ringworm of the nails, though he is unable to explain its mode of action. The application of X rays in this connexion, however, is rather complicated and any overdosage may produce permanent damage. Those who desire to use this method should study the somewhat elaborate technique laid down by McKee in his book ("X Rays and Radium in the Treatment of Diseases of the Skin," second edition, 1927).

A. M. H. GRAY, M.D., F.R.C.P. Lond.,
Physician in Charge of Skin Department,
University College Hospital.

DONATIONS AND BEQUESTS.—Mrs. Caroline Locke Huth, of 45, Upper Grosvenor-street, London, left £20,000 to found and endow a ward for men and boys in the West End Hospital for Diseases of the Nervous System, Regent's Park.—Miss Mary Taylor, Dunfermline, left £1500 for the endowment of a bed in Dunfermline and West Fife Hospital.—Mr. Herbert Francis Lancashire, of The Park, Nottingham, left £2000 to the Nottingham University College, £1000 to the National Lifeboat Institution, £500 each to the Nottingham General Infirmary and the Nottingham Dispensary.—Mr. Robert Lumley Rees, Liverpool, cotton broker, left £3000 to the Royal Infirmary, Liverpool.—Under the will of Miss Grace Levett, Kingston-on-Hull, Yorks, who left £23,424, subject to certain life interests, the testatrix gave one-tenth of the ultimate residue each to the Hull Royal Infirmary, the Hull Victoria Hospital for Sick Children, and the Hull Jubilee Nursing Association.—Mrs. Fanny Gilmore Colman, of Clifton Hall, Clifton, Bristol, left £500 each to the Children's Hospital, St. Michael's, Bristol, the Children's Convalescent Home, Clifton-road, Weston-super-Mare, the Orthopædic Hospital, Grove-road, Redland, Bristol, Bristol Benevolent Institution, and Dr. Barnardo's Home.—Mr. James Bibby, of Holm Hill, West Kirby, Cheshire, left nearly £10,000 to charities, including £1000 each to the Northern Hospital, Liverpool; St. Paul's Eye and Ear Hospital, Liverpool; the Convalescent Home, West Kirby; and the National Children's Home and Orphanage; £500 each to the Cottage Hospital, Hoylake, and the Lear Home, West Kirby.—An anonymous donor has sent a gift of £10,000 to King Edward's Hospital Fund for London.

Special Articles.

ROYAL INSTITUTE OF PUBLIC HEALTH.

WHITSUNTIDE VISIT TO PARIS, AIX, AND VICHY.

THE successful study tour organised last autumn by the Royal Institute of Public Health[1] to the Swiss tuberculosis institutions has been followed up by a visit to the Paris hospitals and to two of the more famous French inland watering places in which upward of 150 Fellows of the Institute and their friends took part. The programme was arranged by Dr. Gustave Monod of Vichy, with the assistance of a reception committee, of which Prof. Léon Bernard was president, and the travelling arrangements were in the able hands of Sir Henry Lunn, who accompanied the party to Paris.

PARIS.

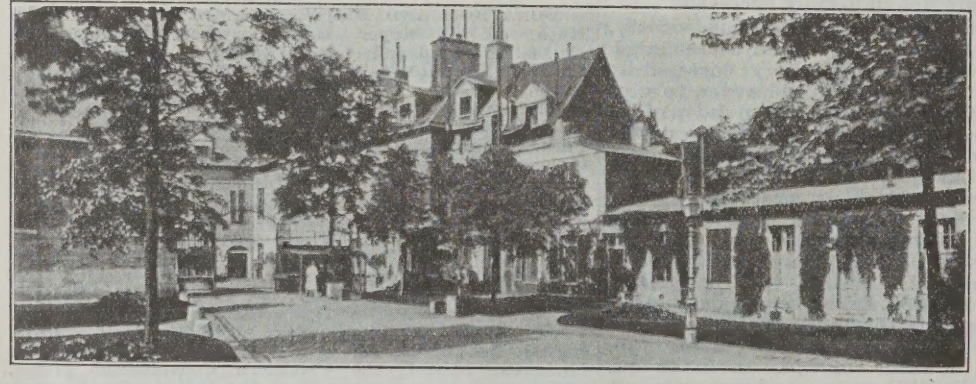
The visit of the Institute to Paris was inaugurated by a dinner to the leaders of the medical profession in Paris, given by Sir Henry Lunn on Sunday, May 20th, at the Palais d'Orsay, which was attended by more than 200 persons. Sir Henry Lunn, who presided, gave expression to the pleasure that he felt at bringing together so many French and English medical men and women who were anxious to know each other and to learn from each other. Prof. Henri Roger, Dean of the Medical Faculty, proposed the health of the King, and Sir Thomas Oliver followed with a tribute to the pioneers of medicine in France, to which Prof. Bernard replied. Dr. Monod, in proposing the health of the chairman, explained, in a neat little speech delivered in perfect English, that the development of the Paris hospitals was hindered by the lack of pecuniary support, due to their association with the State; the hospitals of London, on the other hand, based as they were on voluntary assistance, lacked for nothing—a view for which he was subsequently taken genially to task by some of his colleagues. Amongst the French guests present were Prof. Henri Hartmann, Prof. Jean Sicard, Prof. Georges Guillain, Dr. Paul Garsaux, Dr. Etienne Braissaud, Dr. Desfosses, Dr. M. Robineau, Dr. Pierre Quiserne (of Bagnoles de l'Orne), Dr. Raoul Bensaude, Dr. Paul Ferreyrolles (representing the International Society of Medical Hydrology), and Dr. Louis Blanc (of Aix-les-Bains).

Monday opened with a visit to *La Pitié*, a hospital with 1000 beds on the pavilion system, modernised just before the war. Here Prof. Henri Vaquez received the party and conducted them to a lecture theatre, where the veteran Prof. Jules Babinski demonstrated an admirable film dealing with cerebellar tumours and illustrating many of the characteristic features in diagnosis. In the same theatre a demonstration was given of heart sounds transmitted, after electrical magnification by means of two loud speakers, to large audiences. Dr. Lutembacher, who was present, introduced the film, but left the loud speaker to deliver the lecture in his own voice.

A group taken under the statue of the anatomist Bichat in the forecourt of the Paris Faculty of Medicine.

Photo by E. C. Templier.

At the *Salpêtrière*, which was next visited, Prof. Guillain, the director, conducted the party to Charcot's lecture theatre, where films were shown of myopathy and of Little's disease. A visit was afterwards paid to the Charcot library, containing, besides the priceless collection of neurological books and manuscripts, many interesting relics of the master, including some little humorous sketches made on scraps of paper as people sometimes draw on their dinner menus.



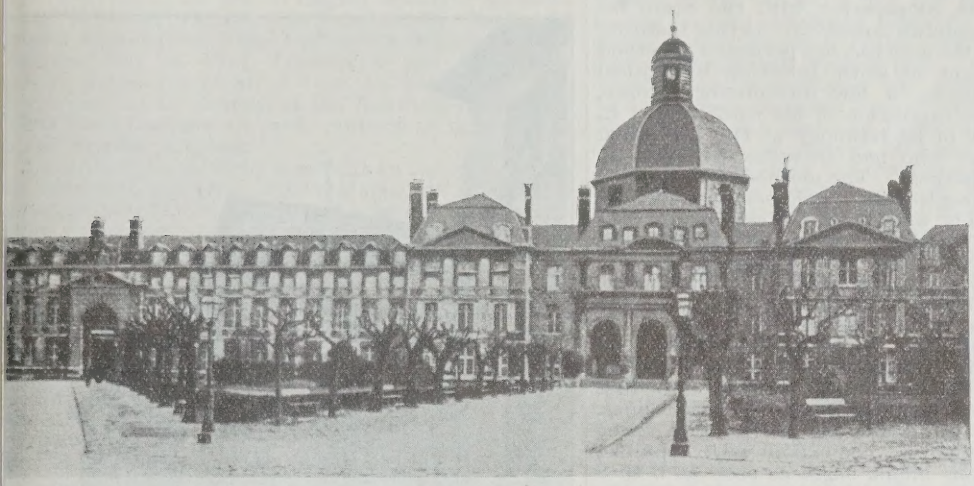
A leafy thoroughfare in the grounds of the Hôpital de la Pitié.*

In the afternoon Dr. Louis Martin and his colleagues took the party round the Hôpital *Pasteur*, which is not, as are the other hospitals, a unit of the Assistance Publique, but was founded in 1888 by international subscription as a memorial to the discoverer of the prevention of rabies. Here there is no isolation in

[1] THE LANCET, 1927, ii., 824; Jan. 14th, pp. 94, 99.

* The five illustrations of Paris hospitals are adapted from photographs in an official volume of the Assistance Publique.

separate wards, but all manner of infectious diseases are treated on the cubicle system, a central corridor allowing the friends and relatives of patients to see and greet them without actual contact. The road



The 17th-century chapel of the Hospice de la Salpêtrière.

was then crossed to the Pasteur Institute, where a wreath was laid on Louis Pasteur's tomb, and in Prof. A. Calmette's absence one of his co-workers delivered a short address on the B.C.G. antituberculous vaccine, his remarks being translated by Dr. L. Field Robinson. This vaccine, administered by the mouth to new-born infants, is regarded as free from risk and able to confer immunity at least up to the age of 5 years. It is now being placed free of charge at the disposal of all maternity hospitals, dispensaries and social organisations in Paris. Work is now being done on subcutaneous administrations.

On Tuesday morning at the Hôpital *Laënnec* a demonstration was given by Prof. Bernard and Dr. Ed. Rist, of the tuberculosis unit, initiated there in the year 1910 on the suggestion of Sir Robert Philip. Dr. Rist frankly admitted that their work at first had no great success, owing to an attempt to do too much, but opportunity came with the war when a private association of visiting nurses offered their services to the hospital dispensary, and other dispensaries were started throughout the department. The French, he remarked, were the most conservative nation in the world, and nothing but a war could have led to such a development. Wards and dispensary being under the same direction, continuity was ensured and patients were never lost to sight. They had inherited from Grancher the system of ensuring the survival of the offspring of tuberculous mothers by separating them at an early age. The child welfare problem had not then been tackled, and Grancher's work began with children over 3 years of age. But Bernard, with the coöperation of Prof. Alex. Couvelaire, undertook the double problem. The consumptive pregnant woman, admitted to the Laënnec, was sent to the Clinique Baudelocque for her confinement, the infant being separated from her immediately after birth, artificially fed for a few weeks in a special department, and then brought back to the Laënnec. If then the cuti-reaction was negative, the infant was sent to one or other of the welfare centres in the villages of central France under medical and nursing supervision. Each centre of 50 children includes a milk station, and is visited periodically by Bernard or his assistants. Contacts are also taken in the hospital but kept apart on a separate floor, the mothers sometimes being allowed to continue nursing the child, wearing a special mask during the act of suckling. The hospital, said Dr. Rist, now has a teaching centre for visiting nurses and post-graduates; the clinical material was ample, for the number of patients treated at the dispensary had risen to 34,000 in the year. Along with Edinburgh and Cardiff, the University of Paris has now recognised a special chair of tuberculosis. With regard to X ray work, every patient, he said, was examined several times during the course of treatment, coördination being ensured by the clinicians being their own radiologists.

The next hospital visited was the *Necker*, with 480 beds, made famous by the fact that it was in its wards that Laënnec discovered auscultation. Prof. Sicard gave a lantern demonstration of lipoidol: first in its harmlessness to experimental animals when injected into the venous system; secondly, in its application to the diagnosis of spinal tumours and affections of the bronchial tree; and finally, as a treatment for fibrositis in its various manifestations. He was followed by Dr. Robineau, who showed on the screen the treatment of fractures by means of bony screws and metal

One of the old wards for incurables in the Hôpital Laënnec.

sleeves, illustrating his thesis that union should be perfect if only complete immobility can be secured.

In the afternoon a tour of the military medical school of the *Val-de-Grâce* was made under the combined tutelage of the Abbé and of the representative of Méd. Inspect. H. Rouvillois. Founded by Anne of Austria, mother of Louis XIV., the hospital has a church full of antiquarian interest, cloisters of rare beauty, and a fascinating museum of war material embracing many campaigns down to the Great War.

The military training is not superposed on the medical, but the student at the end of his first year of medical study enters the school and becomes a soldier.

A visit was then paid to the *Institut Prophylactique*, founded in 1916 in coöperation with the State for the extinction of syphilitic infection. At this Institute Dr. Arthur Vernes, the director, has perfected a method for the measurement of leutic infection by optical methods. After saying a few introductory words, Dr. Vernes left the exposition of his work to Dr. E. Ofenheim, director of bacteriology at the Lewisham Memorial Institute, who had travelled to Paris by aeroplane for the purpose. The method, he said, was one which left nothing to human judgment or error, and was superior in this way to the Wassermann test. More than 100,000 patients had passed through the Institute; there were now 100 centres in France, and 41 countries which had adopted the syphilimetric method. Uncontrolled treatment of syphilis had resulted too often in increasing the incidence of complications, and the syphilimetric method of Vernes afforded the opportunity of an exact control of treatment, so that it was now possible to conduct the course of treatment and dosage on exact lines. The Institute, he said, had no use for the terms secondary and tertiary in connexion with syphilis; cerebro-spinal lesions might begin as soon as 6 to 8 weeks after infection, and it was essential for the disease to be treated continuously on a well-defined plan. After the lecture the ingenious instrument was demonstrated and questions were put as to the evidence for the assumption that the opacity of

Cloistered entrance to the Hôpital Necker.

the serum is an exact criterion of progress in the treatment of the disease.

Wednesday morning was fully occupied by a visit to the Hôpital *Cochin*, which, founded in 1780, has been almost entirely rebuilt, and now ranks among the newest of the Paris hospitals. The visit gave a welcome opportunity of witnessing the methods of teaching clinical medicine in the Paris faculty, and especially those of Prof. Fernand Widal, at whose instance the visit was paid but who was prevented by illness from being present. In Paris students who have completed their preliminary study of chemistry and biology are at once brought into contact with

Street frontage of the Hôpital Cochin.

patients, for "medicine," said the lecturer, "is a practical trade." The morning begins at 9 o'clock with a short theoretical lecture on each of the great clinical syndromes in turn; next comes an hour in the wards with an assistant to superintend, although each student has to work with his own hands, eyes and brain. During the third hour Prof. Widal performs the complete examination of a single patient. "Superficial examination is," he says, "the chief origin of faulty diagnosis," and he prefers to paint one complete clinical picture each day. As an example was shown a patient who had pure asthma without nervous or endocrine symptoms, susceptible to cat's hair, and subject to frequent hæmoclasic crises. Later the party was conducted round a remarkably well-equipped genito-urinary department.

In the afternoon Prof. Roger received the Institute at the *Faculté de Médecine*, when parties were conducted in groups round the lecture theatres and laboratories. Prof. Hartmann took the opportunity of setting out the aims of the A.D.R.M., of which he is president. This is an association, founded six years ago, for the development of medical relations between France and allied or friendly countries. The association works under the presidency of Prof. Roger, with a patronage committee comprising the heads of the medical profession in Paris. The office, known as the Salle Béclard, is convenient of access on the first floor of the faculty buildings, and here visiting medical men and women are sure of finding exact and precise information as to where they can satisfy their needs. During the last twelvemonth 127 visitors have come to Paris to study surgery or gynæcology, 80 general medicine, 52 obstetrics, and other subjects in smaller proportion. Fourteen came to gratify their curiosity as to laboratory work, and 50 desired to know how they could enter for the full medical curriculum and become qualified to

ractise medicine in France. They included representa-tives of at least 30 different countries or nations. 'he Paris faculty decided last year to organise a eries of post-graduate congresses in English with a iew of diverting the flow of English-speaking students om Vienna and Germany to Paris and the provincial 'rench universities. The endeavour is making slow rogress, but as Prof. Hartmann put it, "petit oisson deviendra grand si Dieu lui prête vie," and was evident to Fellows of the Institute that many f the Paris teachers are well equipped to take classes n the English language.

A number of the party went out to the aeroport at *e Bourget* to witness a demonstration of the caisson neumatique of Dr. Garsaux, which is used to reproduce nder experimental conditions the effects of cold and ltitude on airmen.

VICHY.

On Thursday the party left Paris by special train for 'ichy, a run of five hours, the latter half of which is p the fertile valley of the Loire and then of its ributary the Allier, punctuated with old châteaux nd the creamy-white milch cattle seen there alone. n May the journey is throughout a riot of colour ith the yellow broom in full flower. They were eceived on arrival by Mr. Baugnies, chairman of he Compagnie Fermière of Vichy, to which the baths re leased, and by representatives of the local medical ociety, and taken to the Carlton Hotel. At 8 P.M. gala dinner was given in the Salle des Fêtes of the rand Casino, at which Mr. Baugnies, who presided, as supported by Dr. P. Jardet, past president of he medical society, Dr. R. Durand-Fardel, Dr. Guinard, r. E. Willemin, Dr. L. Chabrol, and Dr. Monod. peeches were brief and witty, and the evening ended leasantly with an entertainment by Parisian artistes.

On Friday morning after a visit to the Vichy-État astillerie, at which the natural salt is obtained by

A group taken at the entrance to the Etablissement Thermal, Vichy.

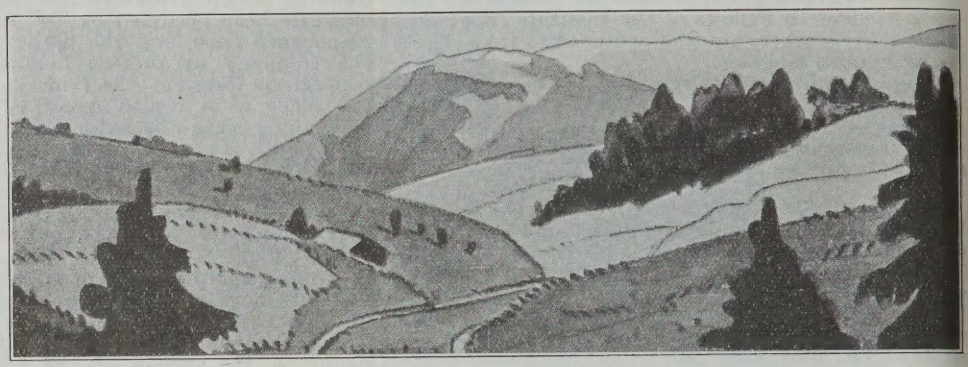
vaporation in vacuo and put up plain in packets and s elegant barley-sugar lozenges, a film was shown t the Vichy-Ciné room illustrating the principal actors of the Vichy cure and the surroundings in hich it is taken. In the afternoon the party was ivided into sections, each of which was conducted ound the new Thermal Establishment by one or other of the local medical fraternity. Vichy, it seems, although well enough known as the *vicus calidus* from Roman times, remained a small thermal town until its glorification in the years 1861–66, when Napoleon III. chose it for his place of residence. It was he who redeemed from the swift-flowing but errant Allier the semicircular strip of land which is now a magnificent wooded park. Napoleon's chalet-dwelling which overlooks the park has for the last 40 years been occupied by Dr. Willemin. It was in Napoleon's time that the baths were first leased to the company at present holding them, to whose courageous foresight the remarkable development of the place as a health resort is largely due. The company's lease was extended last year to run until 1970, and it is proposed to begin at once with the construction of a second thermal establishment, with all the essential equipment, but on lines less lavish than those of the existing house. A large swimming pool and gymnasiums are also in the contemplated programme.

The Vichy waters are plutonian rather than neptunian, and originate, it is believed, from a series of faults in the volcanic strata which are characteristic of the Auvergne. There are five natural springs of which the temperature varies from 16° to 42° C., rising to the surface of the ground within a few hundred yards of one another. There is much subterranean pressure behind them, and one or other of these springs would still, if undaunted, rise above the surface and provide a geyser of no mean appearance, as indeed must have been the case in pre-Roman times. Hotter springs up to nearly boiling-point exist in the near neighbourhood. All these waters have essentially the same composition, the temperature depending solely upon the length of sojourn in the 1000-feet thick layer of marl which overlies the volcanic stratum through which the water rises. Alongside the Celestins spring lies an enormous rock, some 350 by 30 by 20 metres, out of which the water appears to rise, the fact on the contrary being, as Dr. Willemin points out, that the rock has arisen from the water rather than the water from the rock. The composition of this great rock is quite unrelated to the marl in which it lies, and it owes its origin to a gradual accretion of deposit from the cooling water

through the ages. All the waters, too, are practically isotonic with the blood serum, the total mineralisation being roughly 0·7 per cent., a point of some therapeutic importance; the presence of helium and argon along with certain colloid metals is further evidence of their deep origin.

The essential Vichy cure is, of course, the treatment of gastric and hepatic disorders by the systematic drinking of warm carbonated water, and the typical sight is the never-ceasing throng around the springs in the glass-roofed pavilions, each patient bringing his or her own mug or glass to take the prescribed dose of water. The usual course is of 3–4 weeks, and although the residents only number some 20,000 there is an annual influx of more than 150,000 visitors. Apart, however, from the water-drinking, Vichy has considered it prudent to provide all manner of baths and treatments available at other spas; the balneo-therapeutic, gymnastic, and electro-medical equipment compare favourably with those at any continental spa.



A characteristic view of the foothills of Mont Revard at Aix-les-Bains.

Aix-les-Bains.

The journey to Aix-les-Bains was continued on Saturday in the special train which brought the party to Vichy. The cross-country journey proved of unusual interest with the climb out of the Loire Valley into that of the Saône, the transit of Lyon, and the remarkable route up the Rhône Valley to the beautiful lake of Le Bourget, on the north shore of which the Romans discovered hot sulphur springs and built around them the very elaborate system of baths which has only been laid bare during the last few years and is still being excavated. The reception at the station was by the Mayor of Aix, Mr. Henri Clerc, who, when free from official duties, is a distinguished author and dramatist, and after the guests had been allotted to their hotels, they were received by representatives of the local medical society at the thermal establishment and conducted round the baths. It is hardly necessary to dwell on the douche-massage, or Aix douche, which is now a familiar item in the thermal bathing of any well-equipped spa, but the Berthollet cabins were new to many of the party. In them the hot sulphur water, falling from a height, becomes pulverised to produce a warm vapour bath at a temperature of about 42° C., in which the patient stays for 5–10 mins. before or after the massage douche. This bath is also used locally, the spray being directed for 20 mins. on the affected parts by *cornets* surrounding them, the application often being followed by dry massage.

Later in the afternoon, in the Town Hall, Dr. L. Bertier, this year's president of the medical society, gave a short but very comprehensive address on the curative waters, and the local arrangements for hydrotherapy. The baths, he said, were known and visited by the Romans. There were two springs, known as the sulphur and alum sources, both highly radio-active, the former containing a kind of alga known as *baregin*, which facilitated the douche-massage characteristic of Aix treatment. The bathing establishment was owned by the French Government, which put in their own director in charge, and thanks to his initiative there was an early prospect of building an entirely new bathing establishment on the site of the old Roman baths, for which the plans had been put out to competition among architects throughout France. In Aix they were employing 200 masseurs and masseuses, who were taught the elements of anatomy, and who were themselves of necessity of robust constitution, as they worked in the baths from 5 A.M. till noon every week-day. The supply of water to the baths was practically inexhaustible, which was just as well since each douche-massage used up 400 gallons of water, and an enormous volume was required to produce the Berthollet spray, which was a characteristic feature of Aix treatment. The cases coming under medical care of Aix included all forms of chronic rheumatism and arthritis, whether infective or not, neuritis, lumbago, fibrositis, and gout. Dr. Bertier remarked that his colleagues and himself attended at the baths every morning in order personally to supervise the treatment which they prescribed, and to modify it in detail as need arose. This was, he thought, unique at Aix.

In the evening a banquet was given at the Grand Cercle under the presidency of the Mayor, followed by a display of fireworks in the semi-tropical gardens. In an eloquent speech Mr. Clerc sketched the development of Aix, the modern history of which began with the building of the first thermal establishment in 1776 by King Victor-Amédée III. and the popularising of its beauties by the historian and poet, Alphonse de Lamartine. On Sunday the whole party was the guest of the P.L.M. Railway, which conducted it by cog-wheel railway (the earliest of its kind in Europe), or by automobile, to the summit of Mont Revard (5070 ft.) where weather conditions were favourable for a perfect view of Mont Blanc and the mountains of Savoy. Some of the party made the descent on foot in the company of Dr. Forestier, junr., learning from him much of local history and customs. In the afternoon the Zander Institute was visited, and the evening closed with a performance of Charles Dickens's "Cricket on the Hearth," presented by the Société des Casinos.

On Monday morning a visit was paid by steamboat on the Lac du Bourget to the royal abbey of Haute Combe. Here there is a little enclave of Savoyard territory within present-day France, at the foot of the Dent du Chat, in which lie buried the Princes of the House of Savoy. On the way to the lake a halt was made at the laboratory, founded by Lord Revelstoke, which serves a double purpose as public health institute for the control of water and milk, and of a place for clinical investigation of the cases under the care of practising doctors. A glance at the Marlioz establishment, where the hot alum-spring is vapourised for inhalation, and a brief visit to the golf course concluded the official programme, after which members were free to return home or to continue their journey on one or other of several itineraries suggested by the Institute.

This account cannot conclude without a word of appreciation addressed to Dr. T. N. Kelynack, hon. secretary of the Institute, without whose continuous help and coöperation the visit could hardly have been the success which it was.

RECENT WORK ON THE PARASITIC ÆTIOLOGY OF CANCER.

By W. Cramer, Ph.D., D.Sc., M.R.C.S.,
RESEARCH ASSISTANT, IMPERIAL CANCER RESEARCH FUND.

Considerable interest seems to have been aroused in Germany by a paper read at a recent surgical congress by Prof. L. Heidenhain. In this paper Heidenhain claimed to have demonstrated the infective nature of cancer by the experimental transmission of malignant new growths from man to animals, and his results have been accepted by some writers as proof of the parasitic ætiology of cancer. The detailed evidence, on which this conclusion is based has now been published. In a beautifully got-up monograph,[1] Prof. Heidenhain, who is the son of the famous histologist Rudolf Heidenhain, records in great detail the results of the extensive and careful experimental investigation which leads him to conclude that cancer is caused by a living virus. The experimental evidence on which this important conclusion is based consists of the occurrence of tumours in mice which had been inoculated with human cancerous material. The human material was used either fresh or after having been subjected to autolysis. The results are tabulated very clearly and illustrated by a large number of good microphotographs, so that the reader is placed in the position to assess the evidence critically.

The Experimental Evidence.

It is obviously difficult to review briefly the large amount of material presented by the author, but the following data may be given as representing the essential facts. The investigation began in March, 1924, and was concluded in August, 1927. The mice which had been inoculated were allowed to live. Those which died were submitted to a careful post-mortem examination, followed by histological examination of material likely to be neoplastic. The recorded cases of cancer therefore apply only to those animals which died naturally at various periods after inoculation. Most of the experiments were made by inoculating human material; the following figures refer only to these experiments.

Of 1165 inoculated mice 69 developed tumours—about 6 per cent. Taking all his inoculation experiments in which animal and human tumours served as the source of the inoculation, he finds 83 tumours in 1601 inoculated mice—a percentage of 5·2. Of these there were 45 carcinomas and 27 sarcomas; a small number of mice had two tumours. The majority of the tumours did not arise at the site of inoculation. There was no relationship between the type of human tumour inoculated and the type of tumour which developed. Inoculation of a human sarcoma of the humerus, for instances, is followed by a mammary carcinoma in the mouse; a carcinoma of the skin in man, when inoculated into mice, is followed by a sarcoma of the femur in the mouse. The tumours developed in varying intervals after the inoculation—the average interval being about one year.

The Incidence of Spontaneous Tumours.

The question which obviously arises as determining the value of the experimental evidence is: Did these tumours arise as the result of the inoculation? Or would they have arisen anyhow—in other words, are they spontaneous tumours?

Here Prof. Heidenhain has been guilty of a serious error. He quotes a paper by Ascher published in 1912, who attributes to E. F. Bashford the statement that the spontaneous occurrence of cancer in mice is in the proportion of 1:2500—a figure obviously much smaller than that found in Heidenhain's experiments, and on that figure is based the conclusion that the tumours in Heidenhain's series arose as the result of the inoculation. No reference is given to Bashford's statement, which was made in 1905 in the second Scientific Report of the Imperial Cancer Research Fund. Bashford, however, there carefully qualified the statement by saying that it refers only to young mice and predicted that, as in man, a much higher incidence of cancer in mice will be found if animals of all ages are examined. This prediction was fulfilled in a paper by J. A. Murray, published in 1911 in the Fourth Scientific Report of the Imperial Cancer Research Fund. In examining the incidence of cancer in 562 female mice of all ages, of which 92 died with malignant new growths, Murray found that the same statistical considerations apply to cancer in mice as in man; the incidence of cancer increases with increasing age. Murray gave the following table:—

Months.	Neoplasms.	
	Of all tissues.	Of tissues other than mamma.
Less than 9	5	—
From 9–11	12	1
,, 12–14	18	2
,, 15–17	28	2
,, 18–20	12	2
,, 21–23	9 =29	1 =6
Over 24	8	3
Total	92	—

If Heidenhain's results are tabulated in age-groups in a similar way one finds that the incidence of tumours in his inoculated mice increases with increasing age, as they would do if they had arisen spontaneously.

Months after inoculation.	Number of cases of cancer.
3½–5½	5 mice.
6½–9	14 ,,
9½–15	23 ,,
15½–25	27 ,,

The age of mice as supplied by breeders is usually about 2 months. If one assumes that Heidenhain's mice were about 3 months old when inoculated the increased incidence with increasing age corresponds closely to Murray's table, the last group of Heidenhain's 15–25 months comprising the three last groups of Murray's table. The total percentage of the incidence of cancer in Murray's population of female mice from birth to death is 16·3 as against Heidenhain's two figures of 6 per cent. and 5·2 per cent. in a population of mice aged from 3 months till death. A strict comparison is not possible, because Heidenhain's data do not supply the number of mice living at the different age-periods as Murray's do. Murray's figures refer to female mice only in which the bulk of the tumours is represented by mammary carcinomata. No statement has been found in Heidenhain's monograph to indicate the sex of the mice used for inoculation. Assuming that he used an even number of male and female mice and making further the extreme assumption that the incidence of cancer in male mice is so low as to be negligible, Heidenhain's figure for female mice would still fall considerably below that of Murray's figures.

A comparison of Murray's and Heidenhain's tables leaves little doubt that the incidence of cancer in Heidenhain's inoculated mice is no greater than that of normal mice of corresponding age and that his tumours were spontaneous new growths.

The only difference in Heidenhain's group of mice is the high percentage of sarcomata. Murray's figures refer to female mice only in which the percentage of mammary carcinomata is very high, while sarcomata are rare. Murray, moreover, excluded from his figures lymphomatous tumours and adenocarcinomas of the lung as being of doubtful malignancy. Heidenhain includes both these types of tumours. In fact, in his group of sarcomata there are eight cases of a condition described by him as sarcomatosis endothoracica,

[1] Uber das Problem der bösartigen Geschwülste. By Prof. Othar Heidenhain. Berlin: Julius Springer. 1928. Pp. vi. + 153. 41 figs. M.28.

which from his description is clearly a lymphomatous condition strictly confined to the thorax.

Perhaps the most extensive series of observations on the occurrence of spontaneous tumours in mice is contained in the papers published by Miss Maud Slye. This author records "5000–6000 malignant neoplasms" among 61,700 necropsies—that is to say, over 8 per cent.[2] This percentage is again higher than that found by Heidenhain in his inoculated mice. In an earlier paper Miss Slye[3] recorded 87 cases of sarcoma in a series of 12,000 autopsies on mice dying at all ages. She especially emphasised that only tumours of undoubtedly sarcomatous nature were included and that lymphomatous conditions were omitted. The number of sarcomata found by Heidenhain in his stock appears to be distinctly higher than that observed by either Murray or Miss Slye. This is the only significant difference between the recorded observations on the occurrence of spontaneous tumours in mice and the tumours appearing in Heidenhain's series.

Conclusion.

Since the frequency of malignant new growth in Heidenhain's series is not greater than the number of spontaneous tumours recorded in the observations of Murray and Miss Slye, Heidenhain's experiments cease to have the significance which he attaches to them. This conclusion has also been reached by B. Fischer-Wasels[4] in a recent detailed critical review of Heidenhain's results.

MEDICINE AND THE LAW.

Infant Life Protection.

IT is notorious that distinguished lawyers have often been at fault in the making of their wills. They are equally fallible, it appears, in the framing of proposals for legislation. Lord Darling who, after many years of public service as a High Court judge, is now giving valuable help in the improvement of the law, has introduced an Infanticide Bill which ignores that aspect of fœticide which affects the obstetrician confronted with an obstructed labour. The need of amending the law has long been known; Mr. Justice Talbot lately drew attention to it afresh at Liverpool. It is a felony (punishable by penal servitude for life) to procure miscarriage. It is murder to kill a fully-born child. But to destroy a child while it is being born and before it is fully born is no offence whatever. To remove this anomaly Lord Darling's Bill proposes that "whosoever shall in the course of the delivery of a woman of a child wilfully do any act from which the child dies before having an existence separate from that of its mother shall be . . . liable on conviction on indictment to penal servitude for life." This rather clumsily framed proposal takes no account of the fact that occasions may arise when a practitioner has to choose between losing the life of the mother and deliberately destroying the life of the child. As the Lord Chancellor pointed out on the second reading of the Bill, such cases, if they arise, must be safeguarded and protected by legislation. The Bill has therefore wisely been referred to a Select Committee in order that this point, among others, may be considered and the anxiety of the medical profession and of midwives removed. Oddly enough, exactly the same mistake was made 20 years ago. In 1908—a year when infant life protection attracted much attention in Parliament—Lord Robert Cecil introduced a Bill to remedy the same anomaly and made the same omission. Any person (so ran the Bill of 1908) who shall wilfully destroy the life of a child during the birth thereof and before the same shall have been fully born, shall be guilty of felony, and, being convicted thereof, shall be liable to penal servitude for life. In Standing Committee the omission to take account of the medical profession was made good. "Any person who shall wilfully destroy" was altered into "Any person who shall destroy . . . in such a manner that he would have been guilty of murder if the child had been fully born," and the following proviso was attached, "Provided that a person shall not be guilty of an offence under this Act who, by means employed in good faith for the preservation of the life of the mother of the child, destroys the life of any such child during its birth." These words provide a perfectly proper safeguard, and something of the kind is essential if the present Bill is to pass into law.

The Existing Legal Position.

The legal position is fairly clear. There is neither murder nor manslaughter unless the person killed is a person in being. To kill an unborn child while still in its mother's womb is no offence. This doctrine is laid down in Coke's Institutes and is good law still. If the child is born alive and afterwards dies by reason of some felonious act done to it in the mother's womb or in the act of birth, the person who committed that act is guilty of murder. So thought Sir Edward Coke, and, though Lord Hale was inclined to disagree, modern English authorities support Coke's opinion. The last edition of Jervis on Coroners cites a case in point. A man was sentenced at Leicester assizes 30 years ago to 18 months hard labour for manslaughter of a female child; he had struck his wife about the face and body during July; in August the child was born and was found to be severely bruised; it died a few days later. The Court of Criminal Appeal, it is believed, would confirm such a conviction to-day. It is important, of course, to know the legal meaning of "fully born." The law does not deem a child to be fully born—so as to be the possible subject of murder or manslaughter—until its whole body is brought alive into the world having an independent circulation and breathing (or capable of breathing) with its own lungs so that it possesses (or is capable of possessing) an existence independent of connexion with the mother. It has been held that a child was completely born though the umbilical cord was not severed. It has been held, too, that a child born alive can be the subject of murder though it has never breathed. It has been held also that the fact that the child had breathed was not conclusive proof that it was born alive, since it might have breathed and none the less have died before birth.

The Gap to be Filled.

Meanwhile there is a gap between the offence of procuring abortion and the offence of killing a fully-born child. That gap must somehow be filled. Lord Robert Cecil's Bill was refused facilities 20 years ago on the ground that it could hardly be described as non-contentious. It should not be difficult to re-draft Lord Darling's Bill or to equip it with safeguards which are reasonable and universally acceptable, except possibly to those whose religion does not permit the sacrifice of the child in order to save the mother's life. Even from this quarter opposition would hardly arise, since protection must obviously be afforded to medical men who take a different view of their duty.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE: ANNUAL DINNER.

THE annual dinner of this Society, which was presided over by Prof. J. W. W. Stephens at the Café Royal, Regent-street, London, on June 20th, marked the twenty-first anniversary of the Society. The principal guest was the Rt. Hon. L. S. Amery, M.P., Secretary of State for Dominions and for the Colonies, the other guests being Dr. E. Brumpt, Professor of Parasitology in the University of Paris; Dr. W. H. Welsh, Professor of the History of Medicine in Johns Hopkins University; Sir George Maxwell, Deputy Chairman of the Colonial Medical Research

[2] Jour. Cancer Research, 1927, xi., 54. [3] Ibid., 1917, ii., 1.
[4] Münch. med. Woch., June 1st, p. 149.

Committee; Col. T. R. StJohnston, Administrator of St. Kitts, Leeward Islands; Admiral A. Gaskell, Sir Matthew Fell, Air Vice-Marshall D. Munro, Directors-General respectively of the Medical Department of the Navy, Army, and Air Force; Sir James Berry, President of the Royal Society of Medicine; Mr. H. W. Carson, President of the Medical Society of London; Sir Walter Fletcher, Sir James Michelli, and Sir Squire Sprigge, the Editor of THE LANCET.

After the loyal toasts had been proposed from the chair, Prof. Stephens welcomed Mr. Amery, stating that though he might have addressed him as soldier, sailor, linguist, and administrator, he preferred to welcome him as a student of tropical medicine. Mr. Amery's deep interest in the subject had covered more than a quarter of a century, and he was as devoted to the question of proper colonial administration as was the late Joseph Chamberlain, to whose conceptions the two great schools of tropical medicine in London and Liverpool were due. The recent foundation of the Committee of Medical Research, he said, formed an example of Mr. Amery's recognition of the need for that scientific investigation which was the mainspring of medicine and the direct object of the Royal Society of Tropical Medicine and Hygiene. It would be both the pleasure and the duty of the Society to support the Colonial Secretary in all efforts to combat the scourge of tropical diseases.

Mr. Amery, in proposing the toast of the Society, said that no one could occupy the position that he held without recognising not only the intrinsic importance to the State of tropical medicine, but also the urgent necessity of its scientific maintenance for the welfare of the whole of the Empire, where the political and economical importance of the Dominions form a standing element of the British Commonwealth—a fact that was increasingly in evidence. None of the many responsibilities of the Colonial Office, he held, was of greater importance than that where it functioned as a ministry of health. There was a time when the diseases of the tropics were regarded as inevitable concomitants of a tropical climate, for it was only in the last generation that we had learnt that tropical diseases were not more inevitable than the diseases of our own climate and that there was no reason why the tropics should not be made habitable, not only for the natives but for the white men resident there. Once that fact emerged it cast a new light upon our commercial possibilities as well as upon our moral responsibilities arising from Imperial control. Referring to the work of Joseph Chamberlain, he said it was on Nov. 25th, 1898, that the Secretary of State for the Colonies informed the Colonial Office that he had under his consideration the importance of reducing the mortality of tropical climates, and that he had decided, after consultation with the medical authorities on the means of action, to establish a school of tropical medicine in London (soon to be doubled in Liverpool, through the generosity of Sir Alfred Jones) while he also proposed to encourage scientific research in tropical diseases. An act of greater merit had been done by no Secretary of State. Mr. Chamberlain was more immediately concerned with the problem of the white administrators and traders, but the Colonial Office now realised that the problems of white and native health in the Empire were inseparable—the mosquito and the tsetse-fly linked them together. Our conscience and our interest alike were steadily bringing us to the belief that in the health of the native peoples must be sought the master-key for their happiness and prosperity. There was no form of native education so calculated to civilise or strengthen a sense of personal responsibility as education in health, and no theme for mutual coöperation between Government and Government more fruitful, politically as well as physically, than coöperation in the fields of hygiene and sanitation. The medical training of the natives and the evolution among them of a health conscience were now prime objects among statesmen, and this ideal had led to a great expansion of our Empire. When Joseph Chamberlain first realised the importance of tropical health there were on the Gold Coast 21 medical officers; to-day there were 100; in Nigeria 7, to-day 161; in Ceylon 34, to-day 363; in Fiji 8, to-day 68. This was an indication of the development which had taken place in the Colonial medical services, the strength of which to-day was 1700 officers, and it was growing every year. With this growth there had been a wider recognition of the importance of securing men of high personal and professional attainments, while improvement both in salaries and in general conditions of service had been steady. He hoped that in the near future they would be able to create something in the nature of a single Colonial medical service. Just before the war the ordinary salary of medical officers in East and West Africa was from £400 to £500 a year; to-day the salary for West Africa was from £660 to £960, and in East Africa £600 to £900. Before the war the head of the medical department of the Gold Coast received, including duty pay, £1200 a year, while to-day he received £1960. The creation of larger organisations like the West African Medical Service meant greater openings for the right medical men to secure the best posts. A single colonial medical service would enable the best brains in research or administration to be available for those Colonies which needed them most, irrespective of the actual immediate revenue of the Colony.

The general level of medical work in the Colonies, continued Mr. Amery, had never stood so high as it did to-day, while the increased number of officers available enabled more attention to be paid alike to research and the prevention of disease; for colonial medical officers were not left continuously struggling to overtake disease after it had occurred. It was also more possible now to give leave to officers for the purposes of study. Further attention was also being paid to colonial nursing. Anyone who lived under tropical conditions realised the value of good nursing, and he congratulated all those who had devoted themselves for so many years to supplying the Colonial Empire with a sufficiency of fully qualified nurses. Among the striking advances that had been made in tropical disease work were the new hospitals at Singapore, at Accra on the Gold Coast, and at Mulago in Uganda; the forming of a medical school in West Africa, the Sleeping Sickness Commission organised by the League of Nations, and the improvement of the work on malaria—the results of activity at the Singapore base directed against malaria would have been amazing to the last generation. Mr. Amery also quoted figures showing the wonderful fall in the death-rate among European officials in West Africa, and although he had no exact figures to cite in regard to the native population, there was no doubt of the steady improvement in their health, while confidence in our methods and interest in the work itself had also been established among the natives. He concluded by referring to the need for coördination among different countries, and mentioned the fact that two years ago he appointed a chief medical officer at the Colonial Office because he saw that it was necessary for someone to keep in touch with the medical services throughout the Empire, and to link the work with the outside field of scientific knowledge and personal ability which this country afforded.

Dr. Andrew Balfour, Director of the London School of Hygiene and Tropical Medicine, in replying to the toast, referred to the help which the Society had received from its past presidents, Sir James Cantlie, Sir William Leishman, and Sir Patrick Manson, and from the Secretaries. Over £3000, he said, had been raised towards the provision of a mansion house for the Society. Not since the days of Joseph Chamberlain had there been a Colonial Secretary like Mr. Amery, who, it might be said, had breathed a new spirit into the Colonial Office, especially in regard to medical work. In addition to the appointment of a chief medical officer to the Colonial Office, Dr. A. T. Stanton, a Fellow and Member of the Council of the Society, we owed to

him the foundation of the Colonial Medical Research Committee, with which Sir Walter Fletcher had been so closely associated. "Mr. Amery and his able coadjutor, Mr. Ormsby-Gore," concluded Dr. Balfour, "are believers in the personal touch, familiarising themselves with the conditions obtaining in many parts of our far-flung Empire. May I express the hope that it will be possible to extend this personal touch and appoint liaison officers in matters medical and sanitary to act as helpers and advisers to men toiling in isolation and under difficulties."

Lieut.-Colonel W. P. MacArthur proposed the toast of "The Guests," making special reference to Prof. Welsh, who had recently accepted the chair of medical history in the Johns Hopkins University.

Sir Squire Sprigge, replying on behalf of the guests, referred to the assistance which the Colonial Office were always ready to give to those who desired information that would be of practical use.

Dr. P. H. Manson-Bahr, proposed the health of "The Chairman," to which Prof. Stephens briefly replied.

INDIAN MEDICAL SERVICE:

THE ANNUAL DINNER.

THE annual dinner of the I.M.S., which took place on Wednesday, June 20th, at the Trocadero Restaurant, London, under the presidency of Sir Havelock Charles, was well attended, the following officers being present:—

Major-Generals: B. N. Deare, A. A. Gibbs, G. F. A. Harris, R. W. S. Lyons, Sir R. C. MacWatt, J. B. Smith.

Colonels: J. Crimmin, V.C., H. M. Cruddas, C. M. Goodbody, T. A. Granger, C. R. M. Green, J. A. Hamilton, H. Kellock McKay, A. J. Macnab, R. A. Needham, J. J. Pratt, R. G. Turner, F. Wall, C. N. C. Wimberley.

Lieut.-Colonels: A. W. Alcock, F.R.S., W. G. P. Alpin, J. Anderson, S. R. Christophers, Sir Frank Connor, A. G. Coullie, D. G. Crawford, J. M. Crawford, R. H. Elliot, G. H. Frost, H. Greany, J. B. Hanafin, E. C. Hepper, E. C. Hodgson, E. V. Hugo, Dalziel J. B. Hunter, S. P. James, Davenport I. Jones, J. Kirkpatrick, W. H. Leonard, T. M. Macrae, J. Masson, F. O. N. Mell, A. Miller, F. O'Kinealy, J. S. O'Neill, Sir Leonard Rogers, F.R.S., E. R. Rost, S. Browning Smith, R. Steen, Ashton Street, W. A. Sykes, D. W. Sutherland, C. Thomson, G. Sloane Thomson, W. H. Thornhill, E. L. Ward, D. P. Warliker, A. C. Younan.

Majors: Norman Briggs, Sir T. J. Carey-Evans, H. S. Cormack, A.W. Duncan, P. K. Gilroy, N. H. Hume, M. L. C. Irvine, J. C. John, R. N. Kapadia, Rigby G. Lynn, V. Mahadevan, N. B. Mehta, R. V. Morrison, M. A. Nicholson, M. J. Quirke, M. A. Rahman, J. Rodger, E. C. A. Smith, H. Tait Caldwell, D. R. Thomas, G. Y. Thomson, F. R. Thornton.

Captains: M. P. Atkinson, D. P. Bhargava, J. E. Gray, A. C. Hayden.

Lieut. F. T. Harrington.

Dr. N. G. Horner, the Editor of the *British Medical Journal*, was also present as a guest.

It is a feature of these dinners that there should be no speeches, and the speaking was confined to a brief address from the Chairman, wishing prosperity to the I.M.S. In his speech Sir Havelock Charles briefly alluded to the record of the Service before and after the war, and especially to the vast fields for medical research and administrative capacity which lay before the officer of the I.M.S. In reference to the critical times which the Service had gone through recently and the reforms which have been instituted to meet them and to make the career of the officers attractive to the medical profession, the Chairman emphasised the fact that now more than ever an efficient medical service was of the highest importance to the future welfare and progress of India.

At the close of the proceedings Colonel J. Anderson and Colonel J. J. Pratt were asked to accept a piece of plate as a token of the appreciation of the officers of the I.M.S. on their retirement from the position of hon. secretaries of the Dinner Committee, which they had held ever since the inauguration of the annual dinner.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the 1927 health statistics of a group of districts:—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Diarrhœa, &c., under 2 years.	Maternal mortality from childbirth.
Brighton C.B. (140,700)	13·3	13·5	0·91	1·80	2·4	2·4	60/27	4·2	5·7
Chesterfield R.D. (84,320)	21·0	12·2	0·63	1·33	3·2	1·7	82	2·8	6·2
Watford B. (52,580)	15·7	10·3	0·89	1·12	2·0	1·5	53/36	0·0	1·2
Torquay B. (37,400)	15·2	16·2	0·93	1·84	3·2	2·9	51/24	7·0	5·3
Plympton St. Mary R.D. (23,700)	14·4	10·7	0·71	1·21	1·6	2·0	48	0·0	2·8
Chingford U.D. (12,920)	19·8	9·5	0·38	—	—	—	46	0·0	3·9
Thedwastre R.D. (8,301)	14·8	14·3	1·10	1·68	—	4·2	57	0·0	0·0
East Stow R.D. (6,644)	15·6	12·6	0·3	2·0	2·3	2·0	38	19	0·0
Stowmarket U.D. (4,317)	16·2	9·3	0·46	1·4	—	0·9	71	0·0	0·0

C.B. = County Borough. B. = Borough. U.D. = Urban District. R.D. = Rural District. — = No information.

Brighton.

Dr. Duncan Forbes says that for the first time in a normal year the deaths in Brighton exceeded the births—namely, by 19. The same thing occurred in 1917 and 1918, but these were war years, and, in 1918, influenza carried off 367 persons. The diminution of births does not relieve the housing difficulty, because it does not reduce the number of families, nor does it relieve the education committee, because school accommodation has to be found for the larger number of children now born in the outskirts. Dr. Forbes gives a review of the question of slum areas. As long ago as 1877, Dr. Taaffe, the then medical officer of health, reported about 27 slum areas in the eastern part of the town. No action was taken, however, until about 1890–1900, when 459 houses were demolished in three areas, together involving 2158 residents. The decline in the building of new houses began in 1906 when 305 were built, and during the three years 1911–13 only an average of 37 per year were built. In 1918 the corporation began building houses, and have since erected 1294. In 1919 it was estimated that 3000 houses were required to deal with overcrowding and slum clearance. In January, 1928, the position was that two unhealthy areas, each housing some 1000 persons, had been represented, but the rate of progress in slum clearance depends on obtaining better (and cheap-rented) houses for the population of these unhealthy areas. Three schemes to assist housing and rehousing are referred to. Under the Small Dwellings Acquisition Act a proposed Brighton scheme sought to provide three-bedroomed houses of the non-parlour type at a weekly rental of 16*s.* 10*d.*, which is compared unfavourably with a Cambridge scheme to provide similar houses at a rental of 14*s.* 2*d.* A second proposal is to promote private enterprise by guarantees of 90 per cent. of the cost

to building and industrial and provident societies, but this proposal does not favour the Brighton resident anxious for a house to the exclusion of the immigrant. It has been found that houses for the working classes are frequently for sale with vacant possession, and as these are often bought by non-residents they bring no relief to the housing problem. A third proposal under consideration is for the corporation to acquire the houses of tenants willing to occupy new corporation houses and to recondition them for slum tenants, and that the difference between the district valuer's valuation and the purchase-price should be defrayed from the current rates.

Dr. Forbes advocates that the children resident for considerable periods in institutions should be immunised against diphtheria. He also gives examples of the danger of grouping young children. Twenty-four cases of measles occurred in one of the creches with two deaths. Two deaths from whooping-cough occurred in a house where there were five "nurse" children who were infected by the foster-mother's own child. The danger of such happenings weighs heavily, he says, against the advantages of creches, nursery schools, and infant welfare centres. If such occurrences were all recorded it would do much to support the old idea that the best place for a child under 5 is at home with its mother, even if that home be a poor one. Most of the ante-natal work is done for women who have booked with the Sussex Maternity and Women's Hospital, which admitted 74 corporation patients during the year. There were 15 notified cases of ophthalmia neonatorum, of whom one baby lost the sight of one eye.

Of 67 samples of milk examined for tubercle, 10, or 14·9 per cent., gave a positive result. As the result of following-up by the county authorities five cows were dealt with under the Tuberculosis Order, but in as many as four instances no infecting cow was found, probably owing to removal or slaughter before the farms were visited. When tuberculous carcasses of calves or pigs are found at the abattoir information is sent to the medical officer of the district from which they come, and as a result one or two tuberculous cows have been eliminated from herds.

Successful proceedings were taken against three vendors for milk below the standard; a shopkeeper, licensed to sell bottled milk, was fined for selling "loose" milk, and a vendor and his "rounds" boy were both fined because the latter filled a milk-bottle in the street. One sample of cream-cheese contained only 5·2 per cent. of fat, while a sample of lard was found to consist entirely of vegetable fat. Nine samples of "pure" cream were found to contain small amounts of boric acid. A full year's working of the orthopædic scheme has confirmed its great value and full use is made of the scheme by the infant welfare department. The steady improvement in the teeth of the school-children is shown by tabular statements. There is a gradual decrease in the percentage of children referred for treatment and an increase in the percentage accepting treatment.

Chesterfield R.D.

Dr. Herbert Peck states that coal-mining is the chief industry and, with quarrying, gives employment to nearly half the occupied males. The new houses erected during the year numbered 622, 299 municipal, and the rest built with State assistance by other bodies or persons. A scheme for the conversion of privies would have made more progress if the water-supply had been better. There is a large and increasing number of huts on wheels, which pass as caravans, and are built for persons who wish to evade the payment of rates. They are not moved from place to place, but are used instead of proper dwellings. Stricter by-laws are needed for their control. Deaths in the first quarter of the year from influenza and respiratory diseases heavily increased the adult and infant mortality, and a large number of schools were closed during January and February when influenza was rife. There were 21 non-notified tuberculosis deaths, equal to 39 per cent. of the total deaths from this cause.

Watford.

Dr. W. J. Cox reports that of 150 samples of milk examined, 8, or 5·3 per cent., were found to contain tubercle bacilli, and 19, or 12·6 per cent., were found to contain blood or pus cells. Dr. Cox urges the need for the supervision of watercress beds, so as to ensure the purity of their water-supply. He points out that watercress is a valuable food, rich in its vitamin content, and that a considerable quantity is grown in his county (Herts). During the year one bed within the borough was closed because it was considered to be liable to contamination from the public highway. The housing problem still causes a difficulty, and there are over 700 names on the waiting-list. Municipal schemes have, however, relieved the shortage, and private enterprise is making itself more felt, so that there is an improvement. The corporation, since 1920, have erected 1125 houses to relieve the shortage and, in addition, 114 non-parlour houses to rehouse the tenants of the first of the slum areas cleared. A second slum area was demolished in March, 1928, after an unsuccessful appeal by the owners against the clearance of the area. In addition to the houses which they have actually erected, the corporation have issued loans to the amount of £346,250 under the Small Dwellings Act for the erection of 582 houses, and of £93,775 under the Housing Act of 1923 for the erection of 131 houses, both by private enterprise. Dr. Cox points out that 104 of the 825 births were not notified. The Home for Ailing Infants admitted 28 cases (of which six were from outside areas) for an average stay of 93 days. Excellent results are obtained in securing treatment among the school-children. Thus, in only six out of 202 dental cases and 11 out of 129 "tonsils and adenoids" was no action taken by the parents. Dr. Cox emphasises the need for a much more effective system of after-care than that at present provided for mentally defectives after they leave school. The Watford Joint Isolation Hospital serves a population of over 84,000. The cases of scarlet fever admitted are kept for at least six weeks, even in uncomplicated attacks. The chief event of the year was the admission of 44 cases of paratyphoid B from Hemel Hempstead and district. The cases, as a rule, resembled moderately severe cases of ordinary typhoid. At the beginning of the year the hospital contained 14 cases of supposed German measles from Sunshine House, the home for blind babies at Chorley Wood. This institution was visited by two epidemics—namely, in November and December, 1926. Practically all the children and all the staff were affected. The allegation that the second epidemic was due to children being sent home after the first epidemic before they were free from infection led to a Ministry inquiry, which exonerated the hospital from all blame. The illness, which affected the children, in spite of its great infectivity, was of a very mild type, and it was difficult to say whether it was scarlet fever or German measles.

Torquay.

Dr. Thomas Dunlop refers to the many advantages of his district, both as a holiday resort and for invalids, especially those who suffer from asthma or chronic bronchitis, and he states that Torquay is the only British seaside health resort with a complete equipment for spa treatment. Last year was a bad one for sunshine, but Torquay held a fairly good position with 1650·4 hours, which is 138 hours below its average for 28 years.

There is no maternity hospital, but it is expected that the new Torbay Hospital will provide lying-in wards and also facilities for an antenatal clinic. The extension of the borough will enable sufficient drainage to be provided for the isolation hospital, and it has also been decided to provide new administrative and ward accommodation and to install electric light.

The reconstruction of the refuse destructor is well in hand and will enable even temporary tipping, with its fly and rat nuisance, to be dispensed with. The acquisition of powers to obtain an additional supply of water from the South Teign will render the district free from all menace of water shortage even in the driest season.

The Ministry of Health has now sanctioned the clearance of the Pimlico unhealthy area, and the council has made good progress with the housing scheme, 195 houses having been completed and occupied during the year. Since 1920 the council have erected 381 houses, but there are still many applications from necessitous cases. The council supply Grade A (tuberculin-tested) milk for mothers and infants and also in all their refreshment rooms. Dr. Dunlop hopes that a venereal diseases clinic will be provided at the new Torbay Hospital. The council at present pay the railway fares to Exeter of patients who need this assistance. A public abattoir is needed, and the fact that 328 pigs' heads were condemned on account of tuberculosis during the year shows that meat inspection is not what it should be in the surrounding districts. The percentage of pigs affected with tuberculosis was 12. An inspection of the kitchens of the hotels has been instituted under a local Act, and certificates issued in respect of those which comply with the conditions laid down. In July an addition was made to the meteorological records by taking observations of ultra-violet light. The mean daily units of ultra-violet rays as ascertained by the acetone methylene-blue gauge for the last six months of the year were: July, 6·0; August, 5·6; September, 3·75; October, 3·15; November, 2·23; and December, 0·84.

Plympton St. Mary R.D.

Dr. S. Noy Scott says the year has been marked by steady progress in building activity and by the preparation of the Yealm Head water scheme. Originally it was intended to construct a dam at Yealm Head, but now it is thought a more suitable scheme will be obtained by the construction of three weirs across the Yealm and its tributaries. Dr. Scott says the general average of comfort is good, that there is not much poverty, and that a large number of the householders are owner-occupiers. The occupations are not, as a rule, adverse to health.

Chingford U.D.

Dr. Malcolm Barker shows that the accessibility of his rapidly growing residential district has been increased by a new arterial road and an omnibus service. The population at the Census of 1921 was only 9481. The new sewage plant has been so constructed as to be capable of expansion. Automatic compressed-air ejectors raise the sewage from the new low-level sewer 23 ft. After passing through sedimentation tanks it is automatically sprayed on to coke-breeze filters, then passes through humus tanks, and is finally discharged into the Ching brook as a highly purified effluent. Scavenging is made difficult by the erection of isolated dwellings on unmade roads. The refuse destructor is to be enlarged. There are 37 dwellings not connected to the public sewers, 26 of which drain into cesspools. Dr. Barker recommends that some of the watercourses should be piped, and also points out that the numerous pools in the district form breeding-places for mosquitoes and gnats. Under the Chingford town-planning order of 1927 the whole of the district except the built-up portions is included for town-planning purposes.

Thedwastre, East Stow, and Stowmarket.

Dr. S. C. Hounsfield submits a report for these three districts, which are served by one isolation hospital.

Thedwastre R.D. is principally agricultural, but contains one bacon factory and two small brickworks. It is divided into small farms, few of which exceed 300 acres, and there are no large estates. The water-supply is chiefly from wells, and during the year samples from the wells of new houses in three areas were found, upon analysis, to be polluted. The district exports milk and, though the dairies are generally satisfactory, greater cleanliness is needed as regards the cow-sheds and their approaches. The provision of 38 new houses by the council has relieved the housing situation considerably.

East Stow R.D.—The council took action with regard to the insanitary condition of Haughley village. They ordered the discharge of sewage into the street gullies to be discontinued, required the conversion of privy middens into pail closets, and the provision of cesspools for liquid sewage. They undertook the emptying of the cesspools and provided the necessary apparatus. The pail system of closets in the schools is said to be better than formerly, and earth is being more generally used. An epidemic of influenza reached its height in February with several severe cases, and there were three deaths from it. Forty-four new council houses have been erected, but more renovation work of existing houses is needed.

Stowmarket U.D.—The county medical officer made a routine inspection in October and his report commented favourably on the water-supply, the sewage system, and the housing scheme. The council have decided to enforce the provision of galvanised sanitary bins for all houses. There were two deaths attributed to influenza, and during the first week in February some 300 people were laid up from this cause.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 16TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 282 (last week, 365); scarlet fever, 1691; diphtheria, 896; enteric fever, 70; pneumonia, 1005; puerperal fever, 41; puerperal pyrexia, 99; cerebro-spinal fever, 9; acute poliomyelitis, 7; acute polio-encephalitis, 2; encephalitis lethargica, 24; dysentery, 10; ophthalmia neonatorum, 119. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 20 counties: London, 24 (last week, 49; Paddington 1, Marylebone 19, Southwark 1, Wandsworth 3),; Bedford, 8; Buckingham, 4 (Aylesbury 3, Newport Pagnell 1); Chester, 2; Derby, 36; Durham, 56; Hertford, 2 (Bishop's Stortford 1, Watford 1); Lancaster, 15; Lincoln, parts of Holland 5; Norfolk, 2; Northumberland, 9; Nottingham, 1; Soke of Peterborough, 3; Stafford, 17; Surrey, 1 (Mitcham); Warwick, 5 (Birmingham 2, Coventry 3); Yorks, North Riding 2; West Riding, 56; Glamorgan, 14; and Monmouth, 20.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on June 19th-20th was as follows: Small-pox, 75 under treatment, 5 under observation; scarlet fever, 1770; diphtheria, 1950; enteric fever, 18; measles, 711; whooping-cough, 144; puerperal fever, 18 (plus 17 babies); encephalitis lethargica, 67; poliomyelitis, 1; "other diseases," 25. At St. Margaret's Hospital there were 21 babies (plus 14 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was one death from small-pox, 2 (0) from enteric fever, 37 (11) from measles, 7 (2) from scarlet fever, 29 (4) from whooping-cough, 27 (5) from diphtheria, 40 (6) from diarrhœa and enteritis under two years, 43 (3) from influenza. The figures in parentheses are those from London itself.

The two fatal cases of enteric fever occurred at Bath and West Bromwich. Of the 26 fatal cases of measles outside London 6 were reported from Liverpool. Of the 25 fatal cases of whooping-cough outside London 6 occurred at Liverpool and 3 at Gateshead, while the figures for Glasgow and Dublin during the same week were 8 and 4. Five deaths from diphtheria were reported from Birmingham. The death from small-pox was notified from Coventry C.B.

Dr. E. H. Snell, the medical officer of health for Coventry, informs us that a case of small-pox (a woman) was admitted to the City's Small-pox Hospital on May 21st. The husband was advised to have the child contacts vaccinated, but failed to do so. On June 4th the four children were admitted to hospital with mild small-pox; they showed no signs of systemic disturbance. One of them, a girl, aged 9, reported by the parents to have been "a very delicate child since birth," developed acute primary pneumonia and died four days after admission; she had never been vaccinated. Dr. Snell states that the small-pox, which was classified as 'discrete (VI.),' could have had no appreciable bearing on the causation of death.

The number of stillbirths registered during the week was 301 in the great towns, including 53 in London.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdr. H. A. L. Guthrie is placed on the Retd. List.

Surg. Comdr. C. J. O'Connell is placed on the Retd. List with the rank of Surg. Capt.

Surg. Lt. A. E. Phillips to be Surg. Comdr.

H. J. McCann, R. E. P. Cohen, J. T. Rees, and S. J. Savage to be Surg. Lts.

Surg. Comdrs. J. C. Kelley to *Castor*, on recommg., and A. W. Gunn to *Pembroke* for R.M. Infirmary, Deal.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub-Lieut. G. H. Bradshaw to be Surg. Sub-Lt.

Surg. Lt. W. Caithness to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Capt. C. C. G. Gibson to be Maj. (Prov.).

Capt. (Prov. Maj.) A. G. Brown retires, receiving a gratuity, and relinquishes the rank of Prov. Maj.

Capt. R. W. Chapman to be Maj.

Capt. H. J. Bensted to be Maj. (Prov.) and remains secd.

The undermentioned relinquish their commns.: Temp. Capt. J. W. Sutherland and is granted the rank of Maj.; Temp. Lt. J. W. de W. G. Thornton.

Lt. J. D. Borham, half-pay list, resigns his commn.

ARMY RESERVE OF OFFICERS.

Lt.-Col. T. C. Lauder, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Maj. W. P. G. Williams resigns his commn.

Capt. E. G. Snaith (late Leicester R.), to be Lt. and relinquishes the rank of Capt.

ROYAL AIR FORCE.

Wing Commander H. W. Scott to R.A.F. Depot, Uxbridge.

Squadron Leaders R. W. Ryan to Central Medical Establishment; J. T. T. Forbes, to No. 3 Flying Training School, Grantham.

Flight Lt. L. P. McCullagh to R.A.F., M.T. Depot, Shrewsbury.

Flying Officers J. J. MacAndrews and J. M. Ritchie to Headquarters, Air Defence of Great Britain, Uxbridge; and V. V. Brown, to R.A.F. Station, Tangmere.

INDIAN MEDICAL SERVICE.

Capt. D. Clyde to be Maj.

Lt. J. H. Clapp resigns his commn.

COMMISSIONS IN THE ROYAL ARMY MEDICAL CORPS.

A limited number of commissions in the Royal Army Medical Corps are being offered to qualified practitioners under 28 years of age. There will be no entrance examination, but candidates will be required to present themselves in London for interview and medical examination. Applications should reach the War Office not later than 20th July. Further particulars may be obtained from the Under-Secretary of State, War Office (A.M.D. 1), Whitehall, London, S.W.

Correspondence.

"Audi alteram partem."

THE VITAMIN A CONTENT OF COD-LIVER OILS.

To the Editor of THE LANCET.

SIR,—In 1925 you published in THE LANCET[1] an article on the selection of cod-liver oils for medicinal use in which I emphasised the high vitamin value of the oils prepared in Great Britain and Newfoundland. My article evoked a prompt reply from Prof. E. Poulsson, of the University of Oslo, in which he challenged the statement that in general Newfoundland oils possess a higher vitamin potency than those from the chief centre of the Norwegian industry. He presented data derived from tests on 30 samples of Norwegian oil bought openly in chemists' shops, and 12 samples of Newfoundland oil procured by the Norwegian Commercial Information Bureau. Considerable play has been made by those directly or indirectly interested in the sale of Norwegian oils of the fact that I have not answered Prof. Poulsson's criticisms of my article and of certain of the conclusions reached by Dr. S. S. Zilva and myself as a result of our extensive study of cod-liver oils from different sources. Various forms of propaganda have come to my notice. An extreme case is represented by a statement alleged to have been made recently by "the most important agent handling Norwegian cod-liver oil in the United States," to the effect that Dr. Zilva and I were "bought up" by the Newfoundland interest and have since emphasised the superiority of the Dominion oil.[2]

I need not utilise space in your columns to expose such a malicious and untruthful report, but, though I would prefer to remain silent until the close of another investigation now in progress, an article in the May issue of the *Anglo-Norwegian Trade Journal*, the official organ of the Norwegian Chamber of Commerce in London, demands a reply. This article includes a statement, attributed to Prof. Poulsson, that I had made no rejoinder to his letter in THE LANCET of Feb. 6th, 1926, and goes on to say that this is a question of a scientific author contradicting himself and his colleagues without producing new data and without giving any explanation. It is incorrect to say that there has been no reply to Prof. Poulsson's challenge. My colleague, Dr. Zilva,[3] has pointed out that in absence of a fuller description of the method of testing employed by Prof. Poulsson it is difficult to interpret the figures presented by the latter.

It is important to remember that at the time at which this controversy took place the differentiation between the vitamins A and D had not been satisfactorily established. None of the biological methods of assaying the vitamin value of cod-liver oil then in vogue took account of the disturbing influences of vitamin D. In this sense the methods employed respectively by Prof. Poulsson and ourselves are comparable; both were rendered obsolete by the introduction of improved technique in 1924. Incidentally Prof. Poulsson was still advocating the use of a faulty method in July, 1925, in a memorandum to the Permanent Standards Committee of the League of Nations Health Organisation, and it appears that he actually employed it in a series of comparative tests reported this year, though his method was unanimously rejected as defective by a conference of British experts in December, 1925.[4]

An explanation of the discrepancies between the results recorded by Prof. Poulsson and by Dr. Zilva and myself has, however, to be sought. At first sight it might appear that the differences could be attributed to the relatively small number of samples that had

[2] Fishing News, April 21st, 1928, p. 35.
[3] THE LANCET, 1926, i., 463. [4] Ibid., 1928, i., 148.

been examined, and that Dr. Zilva and I had by chance encountered either a series of Norwegian oils of relatively low vitamin value or a series of unusually rich Newfoundland oils. For my part I cannot accept this view. During the past five years I have examined a very large number of samples of cod-liver oil of authenticated origin, and I am more than ever convinced that the vitamin A values of those prepared in Scotland, Newfoundland, and Iceland are usually distinctly higher than those derived from the Lofoten area. My conviction is built up not solely on my own laboratory experience but on opinions I have gathered from many quarters. Perhaps the strongest support I could bring forward, had it not been given to me in confidence, would be the detailed evidence collected from many of the largest consumers of cod-liver oil in this country and the United States. We may be certain that commercial firms using scientific methods of assay which buy yearly many thousand barrels of cod-liver oil, would not have ceased to buy oil from Norway unless they were convinced that the product they were purchasing elsewhere, often at a higher price, was in some important respect superior. Most of the large firms to which I refer maintain laboratories in which routine animal-feeding tests are carried out on oils, and I have personal knowledge that it is on the basis of these tests that changes have been made.

I believe that the cause of the discrepancies between the results of Prof. Poulsson and those of Dr. Zilva and myself is to be found in the differences between the techniques employed. That such differences may be responsible for disturbing results is apparent from the comparative study [5] of the colorimetric and the biological method of determining vitamin A in cod-liver oil. In the report of this study emphasis is laid on the desirability of making comparisons of the vitamin A potency of oils on the basis of the doses required to restore the same rate of growth. The alternative method of comparing the rate of growth upon the same dose of oils is condemned as being incapable of yielding trustworthy results. Perhaps I should point out that whereas the relative values given in this report for the results of my tests were based on the response of growth on 10 mg. daily doses, tests were also made on doses of 2, 4, 8, and 24 mg. of each of the oils.

By itself the report was inadequate to establish the reliability of the colorimetric method (based on principles first introduced by Dr. O. Rosenheim, F.R.S., and myself some years ago), but the conclusion was reached that this method afforded information consistent with that derived from the biological tests.

My own experience with the colorimetric determination has led me to believe that it is probably a more reliable method of assay of vitamin A than the biological test, particularly when the improved form devised by Carr and Price is employed. If I am correct in this view, the results of the past few years indicate even more clearly than those formerly obtained the relatively low vitamin value of the cod-liver oil from the Lofoten area. I refer solely to oils of undoubted origin and history, which are known not to have been blended with oils procured from other areas. Blending, as is well known, often occurs, particularly when the production in one area falls much below normal. I understand that considerable amounts of Icelandic oil have been sold for blending elsewhere during this year's season. I admit to some hesitation over relinquishing the view that spawning reduces the vitamin value of the liver oils, but I am now satisfied that, as far as vitamin A is concerned, the chief cause of variation is probably the quantity and quality of the food of the cod.

Whatever may be the cause of the difference in results, and I am hoping that the investigation with which I am now occupied will throw light on it, I am not satisfied that Prof. Poulsson has disproved the statement that the vitamin A value of the Lofoten oils is, generally speaking, considerably less than that of the oils made in Scotland, Newfoundland, Finmarken, and Iceland.

I am, Sir, yours faithfully,

J. C. DRUMMOND.

THE AMBULATORY TREATMENT OF VARICOSE VEINS.

To the Editor of THE LANCET.

SIR,—I am glad to find that your valuable series of articles on Modern Technique in Treatment now includes a contribution dealing with the ambulatory treatment of varicose veins. Mr. Payne's description of the injection method in your issue of June 9th and 16th is remarkably lucid and should be of great assistance to medical men who are anxious to commence this treatment. A careful perusal of your contributor's work stimulates one, however, to raise one or two points which appear worthy of discussion.

Mr. Payne mentions the discomfort of boot-pressure in relation to malleolar veins which have been chemically thrombosed. As two of my cases have demonstrated, a much more annoying complication is liable to follow injection of these veins—namely, painful œdema of the ankle, which sometimes persists for months in spite of massage. Where unsightly masses of malleolar veins are to be obliterated I now secure this by introducing the sclerosing medium into a vein on the dorsum of the foot. In many instances such veins are not varicose themselves, but they will bear the fluid to those which are. Whilst agreeing with Mr. Payne that the surest method of obliterating all varices is to commence injections distally; when very large femoral ampullæ exist, and the patient's susceptibility has been tested, I invariably take advantage of the reversed flow in these veins to make a proximal descending injection of 2 to 3 c.cm. In this way I have frequently succeeded in obliterating all the varices on the inner side of the thigh and leg by means of a single injection. Finally, with regard to the temperature of the sclerosing fluid, it is not generally known that this has an important bearing upon the reaction following injection. In my own clinic I now regularly employ quinine-urethane solution which is kept at a constant temperature of 105° F., and by so doing I have obtained successful results in several cases which had previously resisted thrombosis.

I am, Sir, yours faithfully,

Swansea, June 19th, 1928. C. J. CELLAN-JONES.

SUBCUTANEOUS EMPHYSEMA DURING PARTURITION.

To the Editor of THE LANCET.

SIR,—The cases of subcutaneous emphysema during parturition, described by Dr. Salmond and Dr. Wells recently in your columns (April 14th, p. 757, and May 12th, p. 988), renew an interest which I have taken for over 20 years in this rare and interesting complication of labour. In all the cases which I have seen recorded it has been presumed that the air had been forced into the tissues after rupture of some pulmonary vesicles. But the record has always stated that no pulmonary lesion had been found.

A case published in the *Stethoscope* (a Bristol medical school journal) in November, 1904, suggested to me an alternative pathology. The report of the case reads as follows:—

"... When the head came in contact with the perineum the pains became stronger. ... At this stage the patient's eyelids suddenly became swollen and she complained that she could not see out of her left eye. The swelling rapidly spread over the face."

Commenting on this case at the time, I wrote :—

"I think the course taken by the emphysema gives a clue to the seat of the lesion. I have seen three cases of fracture of the lacrymal bone, in all of which surgical emphysema occurred, beginning by filling out the eyelids on the side involved and spreading with every attempt to blow the nose, until in one case the malar region and cheek were also involved. In the other two cases the patients were instructed not to blow the nose forcibly, and the emphysema did not spread. Now, when we remember how exceedingly thin the lacrymal bone may be, and how easily broken (in one of my cases the patient had fallen and struck her nose, but not sufficiently hard to produce a black eye), it seems likely that the straining in the case reported had caused a slight laceration of the bone and of the mucosa covering it and continued bearing-down efforts had forced air, first into the eyelids and from there over the extensive regions Dr. Smith details."

Dr. Wells, in describing his case, speaks of the emphysema reaching from the nipples "upwards." But I suggest that it would be worth while interrogating both his patient and Dr. Salmond's with a view to discovering whether, in very fact, the emphysematous swelling did appear at first below and travelled upwards or vice versa.

I am, Sir, yours faithfully,

Bradford, June 22nd, 1928. JAMES PHILLIPS.

ANATOMICAL NOMENCLATURE.

To the Editor of THE LANCET.

SIR,—In your annotation on Anatomical Nomenclature (THE LANCET, May 26th, p. 1081) you express doubt as to whether useful results could be anticipated from a conference between clinicians and anatomists in anatomical nomenclature. Surely it is more important for the student fresh from the dissecting-room to understand his clinical teacher than for a professor of anatomy in Australia to use the same nomenclature as his brother in Berlin. If a committee is to try to evolve order out of the chaos induced by the Basle terminology, let the teachers of clinical medicine and surgery be adequately represented on that committee. When I was on leave in London last year I found that a 20-year-old copy of "Gray's Anatomy" cost more than a brand new one; which speaks for itself, or rather, for London.—I am, Sir, yours faithfully,

H. WILLIAMSON,

Quetta, Baluchistan, June 4th, 1928. Capt., I.M.S.

Obituary.

HENRY POTTINGER KEATINGE, C.M.G., M.B. DURH., F.R.C.S. ENG.,

LATE MEDICAL DIRECTOR, SCHOOL OF MEDICINE, CAIRO.

WE regret to announce the death of the distinguished officer, Dr. Henry Pottinger Keatinge, so long associated with medical developments in Egypt. His death occurred at his residence in Jersey on June 21st, within a few weeks of his sixty-eighth birthday.

Henry Pottinger Keatinge, a son of General R. J. Keatinge, V.C., was born in 1860 and was educated at Uppingham School, proceeding thence to Guy's Hospital in 1879. From Guy's Hospital he qualified as M.R.C.S. in 1883, and proceeding to the University of Durham graduated in medicine there in the same year. His opportunity of active service came promptly with the Egyptian operations of 1884, and from that year for the following six years he served with the Egyptian Army, saw much campaigning on the frontiers, and obtained the Osmanieh Order, the bronze star, and the medal with three clasps. In recognition of this distinguished service he was appointed in 1890, to an official post in the Cairo School of Medicine, where he did excellent work, both professional and administrative. In 1908 he was elected a Fellow of the Royal College of Surgeons of England under Regulation 5, and in 1913 was appointed C.M.G. With the outbreak of war he became the Director of the Cairo Medical School and of the Kasr-el-Ainy Hospital, and for distinguished services in the latter respect was more than once mentioned in despatches and received the Medjidieh Order. With the cessation of hostilities he retired from the Egyptian Government service with a fine record of administrative activity, for which he received the Order of the Nile. Since his retirement he had lived in Jersey.

ARCHIBALD MASON JONES, M.D., CH.B., F.R.C.S. EDIN.

Dr. A. Mason Jones, whose death, at the age of 45, took place on June 11th, was a native of Skewen, in Glamorganshire. He received his medical education at the University of Edinburgh, qualifying M.B., Ch.B. in 1909, and M.D. in 1911. He worked in Edinburgh as clinical assistant to the aural department of the Royal Infirmary, and then settled in general practice at Barry, near Cardiff, despite the handicap of a cardiac affection. He held a commission in the R.A.M.C. during the war, and on the cessation of hostilities, decided to devote himself to laryngology and otology. He accordingly studied for, and obtained, the diploma of F.R.C.S. Edin., and after filling the posts of house surgeon and clinical assistant in the ear and throat department of the Royal Infirmary, Cardiff, obtained a position on the staff as assistant surgeon, and early this year succeeded to the full surgeoncy on the retirement of Mr. D. R. Paterson. He became aural specialist to the Cardiff Education Authority and, in addition to his special work, he continued to act as demonstrator of anatomy at the Welsh National Medical School. His work was always painstaking and thorough, and he proved himself a loyal colleague and a valuable teacher. There is little doubt that he overtaxed his strength and brought on the cardiac troubles which caused his premature death. He was popular with his patients and colleagues, who view with regret the early termination of a promising career.

ROYAL MEDICAL BENEVOLENT FUND.

THE Royal Medical Benevolent Fund endeavours to help the widows of medical men who are living in penury, to assist orphans who are faced with hunger, and to support medical men who in the last days of their lives are in need. An urgent appeal is made for subscriptions and donations, as funds are badly needed to continue this work. Cheques should be sent to the hon. treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1. At the last meeting of the committee 47 applications for assistance were considered, and grants amounting to £792 voted, making the total sum of £5536 in grants this year. This sum is considerably larger than the amount voted during the corresponding period of last year, which shows that increased demands are being made upon the Fund. Of the many applications considered, the following are short notes on two of the cases relieved :—

Mrs. X., an old lady of 72. Her husband died this year at the age of 92. He had held a post as medical officer of health and had to retire in 1919. Although the post carried no pension, he was granted £350 a year under the complimentary title of consulting medical officer. For nine years of retirement this old couple lived on £350 a year. On the doctor's death this payment ceased and the widow was left without a penny. Of her three sons, the eldest suffers from a war disability; he is only able to earn £50, but contributes £25 towards his mother's maintenance. The second son was badly hit in the war, and is now a clerk in Canada and cannot help. The youngest is farming in the Colonies, is married, and has his own family to keep. Voted £36 in four instalments.

Mrs. Y. Her husband was killed in an accident and she was left with four boys. The practice was sold, and with the proceeds she tried to run a boarding-house, which unfortunately failed. Realising what she could out of this failure she rented a house and took in lodgers. Then a devastating and unexpected blow fell upon her. Her husband had been given a loan by a friend, which had always been looked upon more as a gift than as a loan. The friend has also undertaken to pay for the education of one of the boys. The friend died recently, and the executors insisted on the repayment of the loan. The widow offered a cash payment of half the sum, but this was refused. There followed a foreclosure and all the furniture in the lodging-house was seized, the widow's last means of livelihood thereby being lost. Voted £40. With this timely help, and by the generous action of the local panel committee, the widow has been enabled to start afresh.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

ACCIDENTS IN MINES.

ON Thursday, June 21st, the House of Commons went into Committee of Supply on a vote of £116,319 for the salaries and expenses of the Mines Department of the Board of Trade, Mr. DENNIS HERBERT (Deputy Chairman of Committees) in the chair.

Commodore KING (Secretary for Mines), in introducing the Vote, said that during the last five months there had been a very pleasant reduction in the number of both fatal and non-fatal accidents as compared with last year. The death-rate for last year per 1000 persons employed was 1·09 and for the first five months of the year it had been reduced to 1·03. The death-rate per 100,000 shifts worked for 1927 was 0·52. For the first five months of this year it was 0·42. The injury-rate had also decreased. The injury-rate per 1000 persons employed was 4·48 in 1927 and 4·28 in the first five months of 1928. Per 100,000 shifts worked the figures were 1·86 for 1927 and 1·76 for the first five months of this year. He thought that this was an indication of a movement in the right direction. It appalled him to see what a large proportion of accidents could be prevented if the men used due and proper care. He was also impressed by the number of cases in the accident returns where some slight scratch on the hand or arm had, through neglect on the part of the man himself, resulted in death. That was recorded as a fatal accident, whereas if proper care had been taken the life of the injured man would have been in no danger. He asked all who were interested in the mining industry to assist his Department in the campaign of Safety First, which was being carried on throughout the mining areas. He would like to mention the institution last year of a permanent post of Medical Inspector of Mines. That gentleman was at present devoting particular attention to the question of first-aid organisation, and also to the very complex problems of possible injury to health from breathing the dust of highly siliceous rocks, such as quartzite and sandstone. Another important aspect of the health and safety work was the conduct and encouragement of research. This was done in collaboration with the Department of Scientific and Industrial Research and the Medical Research Council through the Safety of Mines Research Board, which was charged with the duty of giving general advice as to the research that should be undertaken into the causes and prevention of mining dangers and with the supervision of approved research work. A new large scale experimental station had been established at Buxton, in a central position, where it was possible for those engaged in the coal-mining industry to see what was being done to lessen danger in the mines. New small-scale laboratories were nearly completed at Sheffield, and when those were completed it would be possible to bring into closer association the small and large scale work. Roughly £50,000 a year was spent in research, quite apart from the capital cost of the new stations, and all but about £2000 of this sum came from the Miners' Welfare Fund. The Research Board had also fulfilled an important function in coördinating safety research carried on by investigators in receipt of grants at several universities. The Board had also arranged a scheme of coöperative research with the Government research organisation in the United States of America by means of an interchange of experts and by mutual arrangements for carrying out research programmes to expedite the work and to reduce the cost. This scheme, which had now been in operation for two or three years, was giving every satisfaction, and steps were being taken to extend it to European coal-mining countries.

Mr. G. HALL moved to reduce the Vote by £100.

After further debate the motion to reduce the Vote was rejected by 190 votes to 112.

THE TEA DUTY.

On Monday, June 25th, the House went into Committee on the Finance Bill, Mr. J. F. HOPE, Chairman of Committees, in the chair.

Mr. RILEY moved an amendment to Clause 1 with a view to reducing the tea duty to 1*d.* per lb.

Dr. VERNON DAVIES said that the idea that tea was a food had at last been dropped by members of the Labour Party. At the present time the working classes in this country drank far too much tea. Instead of using it in the proper manner as an infusion, and perhaps once or twice a day, they made a decoction of it and they thought that the blacker it was the better. From the health point of view he (Dr. Davies) was perfectly certain that that was bad for the community. People became nervous dyspeptics, and he trembled to think what the future of the race was going to be if the population was brought up on stewed tea four times a day. He would consider the Labour Party as better friends of the working classes if they discouraged them from drinking so much tea and tried to do something to encourage the use of milk, which would do the people very much more good.

Mr. J. H. HUDSON said that tea formed a considerable part of the diet of working-class families. It was one of the cheapest beverages they could obtain, and was necessary to make their general diet palatable. The continuance of the present tax on tea was one of the reasons why the working-class housewife left the tea-pot stewing on the hob from one meal to another. If the tea tax were removed working-class families would get tea to drink which would do them no harm.

Mr. HARDIE agreed that black tea was very bad for people to drink. He would never drink it himself, but Dr. Davies had not explained the reason why black tea was drunk in working-class homes. People who had to live on very small incomes could not afford to make tea as it ought to be made. It was a question of poverty. In order to make the tea go as far as possible in hundreds of thousands of homes, when stewing did not make the tea black enough, the housewife put in bicarbonate of soda to draw it still further. If Dr. Davies had been a proper medicine man—(laughter)—he would have taught them the proper way to make tea.

The amendment was rejected by 229 votes to 117.

On consideration of the new petrol tax,

Mr. SNOWDEN moved to reduce the tax from 4*d.* to 1*d.*

The amendment, after debate, was rejected by 237 votes to 115.

HOUSE OF LORDS.

WEDNESDAY, JUNE 20TH.

SLUM CLEARANCE SCHEMES.

THE Bishop of SOUTHWARK asked the Government how many persons in the United Kingdom were now living under slum conditions; how many had been removed from such conditions since the Armistice by slum clearance schemes; how many would be affected by schemes already approved by the Ministry of Health, but not yet carried into effect; and whether H.M. Government had any proposals to hasten the abolition or the improvement of slum property. He said the Government had been carrying out very faithfully their promise to build a large number of additional houses. The success which had been attained in this respect had indeed been remarkable. But the more successful the Government had been in building new houses the nearer they must come to the time when they had to carry out the other part of their promise—namely, to introduce legislation or measures for the clearance of slum areas. They were now in the fourth session of this Parliament. It was therefore natural and reasonable that they should ask the Government to tell them when they proposed to take the steps which were outlined from the Throne at the opening of this Parliament. It was agreed on all sides that where they had a slum they also had a higher death-rate and a lower standard of health than in any other district. He wished to ask the Government if they could give the House any information as to the number of people who were actually living under slum conditions. Unless there was some official statement on the subject exaggerated and highly coloured statements would be made, and indeed had been made time after time. He was quite certain that whatever figures were given they would show that a very large number of people were living under those conditions. Taking London alone, quite apart from the 26,000 people who had been or would be dealt with under the slum clearance scheme adopted by the London County Council, they were told that there were at least 100,000 people living under insanitary conditions. Serious as the problem was, no existing methods of dealing with the housing question were affecting to any large extent the condition of the slums. Men who were earning £3 or under a week could not possibly afford a rent of 20*s.* or 23*s.*, which was charged in many cases for the new houses, quite apart from the inconvenience and cost of moving backwards and forwards from the environs of a big town to the place where the man was employed. The ideal policy was to sweep away the rotten insanitary buildings and then build on the space which had been so cleared, but it was a very slow business. In London a number of approved schemes had not been carried out and a number of slum areas which had been condemned for years still remained as they were. He was not for the moment blaming the Ministry of Health, which was as anxious and keen on this matter as anyone else, but the Minister of Health himself recognised that progress in this respect was very slow. Every year's delay meant another year of suffering and misery and unhappiness.

Lord GORELL said that this was a matter which transcended all questions of party politics, but it seemed to him

nat there was a vast difference between the attitude of ne Conservative Party and that of the Labour Party in egard to this problem. The Government seemed to take ne view that progress was desirable, but that it was one f a great number of matters on which progress was desirable. o the Labour Party, on the other hand, the problem was bsolutely fundamental. They regarded the question of ousing and the complementary question of slum clearance s underlying every one of their social problems. They ould prefer to see every effort and all expenditure directed rst of all to clearing away these conditions, because until nat was done there was no real chance of general social rogress. It was a mistake to look upon this problem as it were wholly urban. While the greatest and most ondensed areas of slums were in the great towns, there ere slum problems in rural areas just as vital to those who ere living in those conditions.

Problems of Overcrowding and Insanitary Conditions.

Viscount GAGE, replying on behalf of the Ministry of lealth, said that the Minister of Health was very sympaetic to the points raised by the Bishop of Southwark. here were really two separate problems: one was overowding and the other was insanitary conditions; and it id not necessarily follow that because insanitary conditions ere remedied overcrowding difficulties would be solved, or ice versa. In the last year for which statistics were availble over 1,000,000 houses were inspected for defects and 3,260 were found to be unfit for human habitation. A rther 352,643, or 30 per cent. of the number inspected, ere found to be unfit in certain minor respects. The ouses, however, were presumably capable of being made fit, nd the local authorities were taking, or had taken, the ecessary steps by issuing notices and other negotiations to ecure their repair. As a result of action taken by local uthorities in 1926, 600,000 houses were repaired and put nto a correct sanitary condition. In connexion with chemes which had been already confirmed by the Minister f Health since the Armistice some 6600 new houses had een completed to replace houses demolished or to be emolished. These new houses would probably accomodate between 29,000 and 30,000 persons. If they educted the 30,000 persons for whom provision had already een made, some 39,000 persons had yet to be provided for. s indicating the considerable difficulty attending slum learance schemes he would point out that since the War 23 schemes had been submitted and 113 had so far been onfirmed. There were 20 schemes which the Ministry knew ere being considered by local authorities. If he compared his with what took place before the War he did not think hat he could be accused of self-complacency in describing as not unsatisfactory. Before the War for a period of bout a quarter of a century only 44 improvement schemes nd 28 reconstruction schemes relating to small areas were onfirmed. It must be borne in mind that these houses had ot suddenly become insanitary since the War, but that hese conditions existed long before the War. As to the uture, the Ministry of Health had before them the whole f the programme connected with the rating and valuation cheme, which would take a great deal of their time as well s a great deal of the time of Parliament. The promise to eal with slum clearances and reconditioning still held good, ut he was afraid that he could not give the dates when egislation would be introduced.

Earl BEAUCHAMP suggested that the time had come hen a new Royal Commission might be set up to go into his matter.

Modern Conditions in Slum Areas.

Lord MELCHETT said that as Minister of Health one of the roblems that was presented to him was the question of lum clearances. He agreed that more ought to be done nd that it was a scandal that in the twentieth century eople should be living under the conditions in which they ved in the slums. But there were two or three practical ifficulties which were extremely hard to solve. One ifficulty was that people who lived in slum areas were by o means so anxious to leave them as some people believed. nother difficulty was that of rehousing people close to heir work, which was a growing demand. He thought hey would have to adopt some method by which people ould be induced to live in blocks of buildings instead of isolated cottages. It was impossible to spread the opulation of great towns like London over endless garden ities, and it was equally impossible to take great industries uch as those which surrounded the Port of London and pread them all over the countryside. What was possible as to recreate in the slum areas modern conditions and nake them comfortable and healthy to live in. He hoped hat the Ministry of Health would not postpone this question r let it be interfered with in any way by the Rating and aluation Bill. Why should they not proceed on adminisrative lines? Local authorities already had very wide owers to deal with slum conditions, and really what was wanted was to make those authorities exercise their powers. There was one amendment of the law which was needed badly, because for want of it clearance schemes were being held up. The compensation which local authorities could pay to the owners of property was very unfair, and the authorities therefore hesitated to put their powers into operation. That was a matter which ought to be dealt with.

The Marquess of SALISBURY, Lord Privy Seal, said that the Government were considering whether they could not find some better way of providing a remedy than the vast schemes of slum clearance and rebuilding. They were difficult, expensive, and presented all sorts of obstacles. If they could only recondition houses which were capable of that treatment a much shorter and cheaper road would be found for achieving their aims. But like all other legislative projects that policy presented great difficulties of its own. He thanked the Bishop of Southwark for his repeated efforts in bringing this matter before the public. Nothing but good could come from those efforts, and he earnestly hoped that they might be attended with success.

THURSDAY, JUNE 21ST.

The National Health Insurance Bill was read a third time, and passed.

TUESDAY, JUNE 26TH.

THE INFANTICIDE BILL: SELECT COMMITTEE.

On the motion of Lord DARLING, the following peers were constituted a Select Committee to consider the Infanticide Bill:—The Earl of Desart, Lord Phillimore, Lord Dawson of Penn, Lord Hewart, Lord Merrivale, Lord Darling, and Lord Hanworth.

LIQUOR (DISINTERESTED OWNERSHIP AND MANAGEMENT) BILL.

On the motion for the second reading of the Liquor (Disinterested Ownership and Management) Bill, introduced by Lord BALFOUR OF BURLEIGH,

Lord DAWSON said that the principle of local option carried with it certain disadvantages, not to say dangers, of its own. Therefore, before it could be employed as a social remedy, the onus of proof lav with considerable weight on the proposer of that remedy. The last thing they wanted to do with popular government was to cheapen elections. They wanted people to regard elections in a serious light, as great occasions, when they were called upon to apply their minds disinterestedly to the problem before them. The fact of ad hoc elections for this or that matter could not but have the effect of cheapening elections in the eyes of the people. Actual experience in regard to elections for Boards of Guardians, and in connexion with the Scottish Temperance Act, showed that relatively small numbers of people went to the polls. When they cheapened elections they got abstentions and small polls. That meant that the elections got into the hands of people who were the least wise, because they were the most fanatical. The people who ran those elections were, to a large extent, people who could not manage their own affairs. Everyone interested in social reform rejoiced that they had had the very valuable experiment at Carlisle to help them, but after 12 years, with every advantage, it could not be said that Carlisle was the outstanding success that it should have been in the circumstances. Taking the test of drunkenness, there appeared to be no fewer and no more cases of drunkenness in Carlisle than elsewhere. Taken as a whole, it was not an inspiring success, nor anything that should tempt one to go very much farther. He could see no end to these ad hoc bodies. Possibly, in a very little while, they would have a new health society asking to have local option in regard to brown bread. There would be no limit to it, and it would be far better to allow the representatives of the people to decide whether or not they were to have these particular restrictions.

Legislation and Drink.

Legislation on drink proved that unless they carried the assent of the people with them they defeated their own objects. No political party had ever taken local option into its programme. There was something in human nature which refused to conform to restricted hours. Let them take the case of Sunday closing in Wales. They found charabanc parties organised on Sundays to carry large bodies of people to the non-restricted areas. What was said to be an occasional drink became an occasion for drink. In London, during the restricted hours, when there was early closing in one district at 9 P.M. and in another at 10 P.M., one could see quite a stream of people walking from one pavement to the other to defeat the law and to get their last drink. Restrictions defeated their own object unless they carried a large amount of public support.

Education and Temperance.

On the other side of the Atlantic they had a terrible problem to deal with. Although the promoter of this Bill might say that the main object of the measure was not

to promote temperance, surely he would not bring forward these far-reaching proposals unless he was assured that they were going to increase temperance. If he would ask himself what measures had done most to promote temperance in this country he would find that education and suasion had done far more than legislation. The improvement in temperance began long before the War, and the figures showed a steady improvement in that respect among the masses of the people. Look where one might, nothing was more striking than the rapid and progressive improvement in the temperance of the people. There had been a great diminution in the consumption of alcohol. He would give one set of figures which showed that in a large house in London 75 per cent. of the people who sat there on one evening were consuming no alcohol at all. The house was fully licensed, but of those who had drink the great majority took beer and light refreshment. The same sort of thing was found everywhere, and the only place where drunkenness seemed entrenched was from time to time behind the motor wheel. The statesmanlike course to pursue if they wanted to increase temperance was to study the causes which worked for temperance, and further them wherever possible. Those causes were (1) the growth of knowledge through education. The educational propaganda of the last 25 years had done a great deal, and foremost among that propaganda was the Band of Hope. Another cause was the great growth in popularity of recreation and games. Above everything else there was the love of health and fitness. There was the realisation of how good alcohol was in its right place, and how they ought not to drink too much, and there was growing up a degree of temperance which left very little to be desired. There had been a striking improvement in the public houses in this country wherever one went, with the exception of the slums. In some of the newer public houses around London food and coffee were provided, and non-alcoholic drinks, with games and amusements, and the management were not paid any commission on the amount of alcoholic drink. It was along such lines as those that they ought to proceed. At present that was discouraged by the licensing authorities, but by encouraging these houses and educating people, temperance, which was rapidly growing, would reach its goal far sooner than by drastic and restrictive legislation.

A motion by Lord BANBURY for the rejection of the Bill was carried by 67 votes to 24.

HOUSE OF COMMONS.

THURSDAY, JUNE 21ST.

Treatment of Tuberculous War Pensioners.

Sir WILFRID SUGDEN asked the Minister of Pensions whether full advantage was being taken of sanatoria attached to village settlements for the treatment of war pensioners suffering from tuberculosis.—Major TRYON replied: Treatment for pensioners suffering from tuberculosis is secured through the local health authorities, who normally make use of their own sanatoria, approved for the purpose by the Ministry of Health. This practice secures that local facilities are utilised to the full and is also consistent with the policy (so often pressed upon me) of treating pensioners, as far as possible, near their own homes. Cases of this class which are likely to be suitable for, and to benefit from, ultimate residence in a village settlement after any course of treatment required, will, I am advised, at the present time be increasingly few among pensioners whose tuberculosis is directly traceable to their war service, having regard to the stage of their complaint, age, previous occupation, habits of life, and other factors. As such cases arise, while my powers are necessarily limited in the case of this, as of all other disabilities, to the provision of the treatment required, treatment in a sanatorium attached to a village settlement may be preferable to the normal arrangements of treatment in the sanatorium of the local health authority, and I am prepared to continue to give reasonable facilities for the treatment of suitable cases accordingly.

Shortage of Water in Nantwich Area.

Mr. AMMON asked the Minister of Health whether his attention had been drawn to the serious shortage of water, with the resulting danger to public health, at Haslington, in the rural district of Nantwich; and what action had been taken by the local authority concerned and his department with a view to a more adequate water-supply being afforded residents in the district referred to.—Mr. CHAMBERLAIN said that his attention had been drawn to this matter. The local authority had under consideration a proposal for providing a further supply of water, and officers of his Department was conferring with representatives of the local authority on the proposal.

Welfare of Blind Persons.

MR. GROVES asked the Minister of Health if he had received overtures from certain local authorities appealing to him to amend Section 1 of the Blind Persons Act, 1920, so as to provide for the payment of pensions to the unemployable blind at 30 years of age instead of 50 years of age; and whether he was prepared to accept such proposal.—Mr. CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative, and to the second part in the negative. I may, however, add that I have requested the Advisory Committee on the Welfare of the Blind to investigate the whole question of assistance to the unemployable blind, and have issued a circular to the appropriate local authorities asking for certain information desired by the Committee for the purpose.

Feeding of Necessitous School-children.

Mr. GROVES asked the President of the Board of Education the number of school-children fed at the school centres in the West Ham, East Ham, Leyton, and Walthamstow areas for 1924, 1925, 1926, 1927, and 1928, respectively, as far as possible.—Lord EUSTACE PERCY replied: The following is the information asked for:—

Area.	1924–25.	1925–26.	1926–27.	1927–28.
West Ham.. ..	1251	1242	2789	4172
East Ham	438	351	535	500*
Leyton	134	115	272	358
Walthamstow ..	196	163	570	585

* This figure is approximate only.

Boy's Death after Vaccination.

Mr. ROBINSON asked the Minister of Health whether he had received any report regarding the death of John Flanaghan, of Keighley, aged 10, who was vaccinated as a condition of going to a boys' camp, by Dr. Villey, on May 12th, became very ill on the 26th, was unconscious on the 27th, and died on the 29th from meningitis; whether any inquiry was held into the death of this boy, who was perfectly healthy when vaccinated; and, if so, what was the result.—Mr. CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. So far as I am aware no inquiry was held into the death of this boy, but my Department have been in communication with the certifying practitioner. I am informed that no post-mortem examination was held, and that the certified causes of death were: (1) (*a*) acute meningitis, (*b*) tonsillitis; (2) vaccination.

Small-pox in England.

Mr. WALTER BAKER asked the Minister of Health the number of cases of small-pox reported in England during the present year; and in how many instances there had been fatal results.—Mr. CHAMBERLAIN replied: Cases of small-pox, totalling 6607, were notified in England, excluding Monmouthshire, during the present year up to June 16th. The number of deaths up to the end of May in respect of which small-pox appeared in the medical certificate as the cause, or one of the causes, of death, was 46. It should be added that these figures are at present provisional, and that no case of small-pox has been notified this year from a port sanitary district.

Small-pox among Vagrants.

Mr. SMITH-CARINGTON asked the Minister of Health whether, in view of the increasing prevalence of small-pox among casuals, he would consider the enforcement of a stand-still order in respect of all vagrants.—Mr. CHAMBERLAIN replied: The number of cases of small-pox among casuals has recently shown a tendency to decrease, but apart from this I am satisfied that my hon. friend's proposal, which I have already considered, would not have the effect desired.

Accidents in Mines.

Mr. BARKER asked the Secretary for Mines the number of fatal accidents and the number killed in the mines of the United Kingdom for the year 1927; the number killed by falls of roof and sides during this period; and the total number seriously injured by all causes during the year 1927.—Commodore KING replied: During the year 1927 there were 1028 fatal accidents at mines under the Coal Mines Act, resulting in 1128 deaths, of which 565 deaths were due to falls of roof and sides. During the same period, the total number of persons seriously injured by accidents at these mines was 4692.

Mr. LAWSON asked the Secretary for Mines the number of accidents, fatal and non-fatal, in the mining industry for the years 1925 and 1927.—Commodore KING replied: During the year 1925, there were 1050 fatal and 177,609 non-fatal accidents at mines under the Coal Mines Act, resulting in 1136 deaths, and disablement for more than three days to 178,060 persons. In 1927, 1028 fatal accidents caused 1128 deaths and 172,883 non-fatal accidents caused injuries to 173,449 persons.

Artificial Sunlight Treatment.

Sir ROBERT THOMAS asked the Minister of Health the number of existing centres for artificial sunlight treatment in Wales and Monmouthshire, distinguishing those established by local authorities directly, those of voluntary agencies, and school clinic light centres, respectively.—Mr. CHAMBERLAIN replied: I am informed that two local authorities in Wales and Monmouthshire have established centres for artificial light treatment, and one other local authority is about to do so. Four such centres have been established by the Welsh National Memorial Association and three by other voluntary bodies, one of which is utilised by six local authorities in North Wales. One of the centres established by a local authority is used for the treatment of school-children as well as for children under school age.

Public Motor Vehicles and First-aid Outfits.

Mr. DUCKWORTH asked the Minister of Transport whether his promised Road Transport Bill provided for the necessity of motor vehicles licensed to carry passengers being fitted with first-aid outfits; and if not, whether he would consider the desirability of making it compulsory for such outfits to be installed in all such vehicles in the interests of public safety.—Colonel W. ASHLEY replied: The Draft Road Traffic Bill which I circulated last year would empower me to prescribe the conditions with which the equipment of motor omnibuses and motor coaches would have to comply, but I doubt whether it would be considered reasonable to make the carrying of first-aid outfits by all public service vehicles compulsory.

Claims for Dental Benefit.

Mr. RHYS DAVIES asked the Minister of Health if he had any information to show whether claims to dental benefit by insured members on any approved societies had now reached the anticipated maximum or whether such claims still continued on the increase.—Mr. CHAMBERLAIN replied: General statistics are not available to show the rate at which claims to dental benefit are now being received by approved societies, but I am informed that some, at any rate, of the larger societies have found the claims during the present year to be fairly steady in number, or even to show some tendency to decline.

MONDAY, JUNE 25TH.

Welsh Board of Health.

Sir CLEMENT KINLOCH-COOKE asked the Minister of Health his reasons for abolishing the post of Chairman of the Welsh Board of Health.—Sir KINGSLEY WOOD, Parliamentary Secretary to the Ministry of Health, replied: On the retirement of Sir Thomas Hughes from the Chairmanship of the Welsh Board of Health the position was reviewed, as is the case from time to time with all sections of my Department, in order to make sure that a proper relation existed between the personnel engaged and the work falling upon the Board. This review showed that the bulk of the Board's work is done, and done satisfactorily, by the members in their individual capacity, and meetings of the Board for collective deliveration are only rarely held. In these circumstances my right hon. friend felt that the employment of four higher officials on the Board was no longer justified and that the work could quite well be done in future by three. I may add that the Ministry of Health Act, 1919, empowers my right hon. friend to appoint such officers as he thinks fit to constitute a Board of Health in Wales, and it neither specifies any number nor lays down that there shall be any chairman.

TUESDAY, JUNE 26TH.

Fresh Water on Merchant Ships.

Lieut. Commander KENWORTHY asked the President of the Board of Trade what were the regulations in force regarding the taking on board of fresh water for cookng and drinking in merchant ships; if he was aware that it was the practice of certain ships' captains to fill up the fresh water tanks with river water which was not pure; and whether he would take steps to ensure the taking of an adequate supply of fresh and pure water in British and foreign ports respectively.—Sir P. CUNLIFFE-LISTER replied: I am sending the hon. and gallant Member copies of the provisions relating to the supply of water on merchant ships, and he will see that in home ports the water is subject to inspection by officers of the Board of Trade, and that at any port the water has to be examined if a complaint is made by three or more members of the crew, and any defects have to be put right. I am aware that river water is sometimes taken. It is the duty of a master to take good water whenever it is available, and if particulars are given of any case in which this is not done, the matter will be inquired into.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At recent examinations the following candidates were approved:—

THIRD EXAMINATION FOR M.B., B.CHIR.

Part I.: Surgery, Midwifery, and Gynæcology.—M. E. Albury, N. R. Barrett, H. F. Bateman, W. A. G. Bell, F. Bush, S. S. Chesser, E. Clayton-Jones, G. C. Dewes, A. J. Dix-Perkin, W. J. G. Drake-Lee, J. StC. Elkington, W. A. Elliston, P. H. Fox, E. L. Graff, C. J. Grosch, R. Hodkinson, S. H. G. Humfrey, S. D. Isaacs, W. P. Jones, L. W. A. Lankester, P. G. Levick, J. C. F. Lloyd-Williamson, A. Maberly, A. A. Miles, J. K. Monro, J. R. Peacock, L. S. Penrose, J. B. A. Reynolds, A. M. Rhydderch, A. M. Roberts, W. H. Scott-Easton, C. W. Shaw, H. J. Simmons, W. H. Simonds, E. T. O. Slater, T. R. Stevens, H. H. Stewart, H. S. Taylor Young, J. F. Varley, J. Vaughan Bradley, H. S. Waters, L. B. Winter, F. W. J. Wood; M. H. D. Carr, M. Leathes, J. R. Lees, and M. A. Wilcox.

Part II.: Physic, Pathology, and Pharmacology.—M. C. Andrews, W. R. Ashby, N. R. Barrett, D. H. Belfrage, W. Buckley, S. S. Chesser, H. T. Cox, W. J. G. Drake-Lee, J. StC. Elkington, E. G. Frewer, T. O. Garland, R. M. Gilchrist, F. H. Gillett, J. C. Gordon, R. A. P. Gray, L. J. Haydon, J. H. Hopper, M. C. Hounsfield, L. R. Janes, T. E. Lamech, J. M. Lees, E. W. Lindeck, W. J. Lloyd, R. A. McCance, D. J. MacMyn, W. E. Mashiter, A. A. Miles, T. St. M. Norris, M. D. Nosworthy, R. E. M. Pilcher, J. C. C. Poole, E. J. Pye-Smith, E. G. Recordon, A. M. Rhydderch, F. A. Richards, A. M. Roberts, R. W. N. Robins, R. P. Ross, H. Scudamore, L. Shillito, F. Smith, T. R. Smith, W. Smith, E. T. C. Spooner, T. C. Stevenson, G. R. S. Stewart, H. H. Stewart, G. S. Storrs, J. R. H. Towers, H. S. Waters; A. G. Clogg, C. P. Giles, E. M. Hoskin, and M. P. Shackle.

SOCIETY OF APOTHECARIES OF LONDON.—At a recent examination the following candidates passed in the undermentioned subjects:—

Surgery.—K. J. M. Graham, Charing Cross Hosp.; T. A. P. Proctor, Birmingham; A. F. Quarmby, Birmingham; S. M. Rahman, Calcutta and Middlesex Hosp.; and W. Ziv, Bâle and London Hosp.

Medicine.—P. C. Basu, Calcutta; H. C. Clifford-Smith, Charing Cross Hosp.; S. M. Rahman, Calcutta and Middlesex Hosp.

Forensic Medicine.—M. K. Bryce, London Hosp.; and A. F. Quarmby, Birmingham.

Midwifery.—H. H. Jackson, Manchester and Charing Cross Hosp.; C. P. Madden, St. Bartholomew's Hosp.; and H. Murkus, Birmingham.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: K. J. M. Graham and William Ziv.

UNIVERSITY OF DURHAM.—At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR M.B., B.S.

Pathology, Bacteriology, &c.—Wilfred Hall.

THIRD EXAMINATION FOR B.D.S.

Pathology, Bacteriology, &c.—John Chalmers.

KARLSBAD POST-GRADUATE COURSE.—The annual post-graduate course with special reference to balneology will be held from Sept. 23rd to 29th. Twenty-seven lectures will be given by well-known authorities from all countries on many aspects of medicine. Among the British lecturers will be Prof. Hugh MacLean, who will speak on the treatment of gastric and duodenal ulcers with alkalis in large doses, and Dr. George Graham, who will discuss the cause of the lowered tolerance for sugar among diabetics. Special concessions are being given by the railway companies to those taking the course. Further particulars may be obtained from Dr. Edgar Ganz, of Karlsbad.

LIVINGSTONE COLLEGE.—Dr. G. C. Low presided at the commemoration day celebrations at Livingstone College, Leyton, on June 15th. After a brief résumé of the advances in tropical medicine during the last 40 years, he drew attention to the importance of special training in this branch of medicine to all who go abroad. Such training the College provided for missionaries and others and every year its old students testified how the teaching obtained there had enabled them to save life, had tided them over difficulties, and had helped them to preserve their own health and keep fit when others were ill and dying. Students of the College were treating yaws, sleeping sickness, and leprosy under the direction of Government Medical Service in Africa and other lands. It was astonishing, said Dr. Low, how knowledge of a simple fact might influence the progress of a disease and how nursing might make all the difference between life and death. The Principal reported that 1020 students had passed through the College and begged missionary societies to send their candidates for training. The sum of £400 is needed to close the financial year without a deficit on the year's working.

UNIVERSITY OF SHEFFIELD.—At a congregation to be held on July 11th in connexion with the centenary of the foundation of the medical school in Sheffield, the honorary degree of D.Sc. will be conferred upon Dr. H. H. Dale, F.R.S., Prof. A. J. Hall, Sir Frederick Hopkins, F.R.S., Sir Thomas Lewis, F.R.S., and Prof. Otto Warburg.

UNIVERSITY OF GLASGOW.—At a graduation ceremony held on June 20th the honorary degree of Doctor of Laws was conferred on Prof. George W. Crile, of Cleveland, Ohio, past-President of the American College of Surgeons. The degree of M.D. was conferred on Frederick Robertson Martin for a thesis entitled A Study of Kretschner's Types in the Psychoses.

UNIVERSITY OF OXFORD.—The Radcliffe Prize, of the value of £50, is awarded by the Master and Fellows of University College every second year for research in either human anatomy, physiology, pharmacology, pathology, medicine, surgery, obstetrics, gynæcology, forensic medicine, or hygiene. It is open to all graduates of the University who have proceeded, or are proceeding, to a medical degree in the University. Candidates must not have exceeded twelve years from the date of passing the last examination for the Degree of Bachelor of Arts. Memoirs should be sent to the Secretary of Faculties, at the University Registry, on or before Dec. 1st, 1928; the award will be made in March, 1929. No memoir for which any University prize has already been awarded is admitted to competition for the prize.

UNIVERSITY OF LONDON.—At a meeting of the Senate on June 20th, Sir Gregory Foster, Provost of University College, was elected Vice-Chancellor for 1928–29 in succession to Sir William Beveridge. A unanimous and cordial vote of thanks was passed to Sir William Beveridge for the conspicuous services which he had rendered to the University during his tenure of office. The degree of D.Sc. in Anatomy was awarded to Miss Ida C. Mann, F.R.C.S., for a thesis on the Development of the Human Eye, and the degree of D.Sc. in Physiology to Mr. C. H. Best, of the National Institute for Medical Research, for a thesis on the Effect of Insulin on the Dextrose Consumption of Perfused Skeletal Muscle.

University College.—Dr. R. J. Brocklehurst has been appointed lecturer in the department of physiology and biochemistry, and Dr. Marion G. Eggleton assistant in physiology and biochemistry.

GRANT MEDICAL COLLEGE, BOMBAY.—The annual report shows that several new schemes have taken shape at the college during the year. The building for the new pathology and bacteriology departments, which are to be amalgamated, has been begun, and will contain the pathological museum, and bacteriological and clinical laboratories, the instalment of an up-to-date refrigerator also forming part of the scheme. The Memorial Tablet of the Sir Currimbhoy Memorial Dental College and Hospital was unveiled in February, and this institution will provide instruction in dental surgery and dental relief. During 1927–28 there were 418 regular students at the college.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.—The eighty-seventh annual meeting of this Association will be held from July 11th–13th, under the presidency of Prof. J. Shaw Bolton, at the West Riding Mental Hospital, Wakefield. A business meeting will be held at 10.30 A.M. on the 11th, and at 2.30 P.M., Prof. Shaw Bolton will give his presidential address, entitled the Evolution of a Mental Hospital—Wakefield, 1818–1928. The two other days will be devoted to the reading of papers and demonstrations. A detailed programme may be had from the general secretary, Mr. R. Worth, Springfield Mental Hospital, near Tooting, London, S.W. 17.

MEDICAL GOLFING SOCIETY.—The summer meeting was held on June 19th at Walton Heath when competitors were the guests of Lord Riddell. The results were as follows: THE LANCET Challenge Cup: T. A. Torrance, 3 up. Henry Morris Challenge Cup: T. A. Torrance, H. T. P. Kolesar, H. Chapple, C. Apperly, and Murray Thomson (tied at 1 up). Milsom Rees Challenge Cup: Murray Thomson, 5 down. Class I.:—First Prize and Second Prize: T. A. Torrance and H. T. P. Kolesar (tied at 1 up). Best Last Nine Holes: H. T. P. Kolesar, W. Jagger, and H. D. Gillies (tied at 2 up). Class II.:—First Prize and Second Prize: H. Chapple, C. Apperly, and Murray Thomson (tied at 1 up). Best Last Nine Holes: H. L. Hatch, A. C. Palmer, and Haldin Davis (tied at 2 up). Foursomes:—First Prize: T. A. Torrance and Sir K. Goadby (won at 2 up); Second Prize: W. Jagger and H. G. Hill, W. R. Bristow and H. T. P. Kolesar (tied all square).

EPSOM COLLEGE: A SUBSTANTIAL BEQUEST.—After making generous provision for his domestic staff and gifts to friends, Inspector-General Henry Hadlow, R.N., left practically the whole of his estate to various medical charities, including £10,000 stock to Epsom College for the creation of a pension fund for medical men and their widows. He also gave £8500 to the Royal Portsmouth Hospital and £100 to the Portsmouth Eye and Ear Hospital.

THE King has sanctioned the following promotions to the Venerable Order of the Hospital of St. John of Jerusalem:—As Commanders: Col. Harry Thornton Challis and Mr. John Willett. As Officers: Lieut.-Col. William Blackwood and Maj. William Owen Evans.

LONGEVITY OF INCURABLES.—At the festival dinner of the Royal Hospital and Home for Incurables at Putney it was stated that, despite their infirmities, some of the inmates had been in the home 20, 30, and even 50 years.

SURREY COUNTY SANATORIUM, MILFORD. — The Minister of Health, Mr. Neville Chamberlain, will formally open this sanatorium on Friday, July 20th, at 3.30 P.M. The building has been designed to accommodate 300 patients and the necessary staff, and cost about £200,000.

MIDDLESEX HOSPITAL REBUILDING.—On June 26th the Duke of York, accompanied by the Duchess, laid the foundation-stone of the west wing of the new Middlesex Hospital building. Prince Arthur of Connaught, chairman of the hospital, announced that £405,500 has so far been contributed towards the cost of reconstruction, which is estimated at £1,001,670. The sum of £200,000 has been given anonymously for the building of the new nurses' home.

NATIONAL HEALTH INSURANCE.—Arrangements are being made under which arrears of Health Insurance contributions will be excused for any week, after July 1st, 1928, during the whole of which the insured person proves that he was available for but unable to obtain employment. Arrears are also to be excused for periods of incapacity for work through sickness, whether benefit is claimed or not, provided that notice of the sickness is sent promptly to the approved society. Instructions as to the procedure to be adopted in order that this concession may be obtained will be given at any local office of the Ministry of Labour.

ADDRESS TO THE GOVERNOR-GENERAL OF THE IRISH FREE STATE.—The Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland have each presented an address of welcome to Mr. James McNeill, Governor-General of the Irish Free State. In its address the College of Surgeons expressed its satisfaction with the settlement of the registration question, and its assurance of hearty coöperation with the Government in all matters affecting the public health. In his reply the Governor-General thanked the College for its welcome, and added that its "readiness to coöperate in matters affecting the public health and the public welfare would be recognised by all who appreciated the standards of duty which the medical profession was at pains to inspire in, and exact from, its members."

A CENTRAL MEDICO-LEGAL INSTITUTE.—In a leading article on Status Lymphaticus in THE LANCET of May 26th (p. 1078) we noted that "the recent Coroner's Act seems to have had the unfortunate effect of diminishing the number of examples of sudden and violent death which are subjected to expert examination, and emphasis is laid once more on the grave defect in having no central institute in London where all the medico-legal work should be concentrated in the hands of experienced pathologists, who might have some chance of getting to the bottom of this and similar problems." At a meeting of the London County Council on June 19th Lieut.-Colonel J. B. Dodge asked the Chairman of the Public Health Committee: (1) Whether he had had his attention called to a leading article in the press in which emphasis was laid on the grave effect of having no central institute in London where all the medico-legal work should be concentrated? (2) Whether his attention had been drawn to discussions upon this matter at the Medico-Legal Society? (3) In view of this, whether he would ask his official advisers to prepare a memorandum on the subject for the information of the members of the Council?—Dr. Barrie Lambert, the Chairman of the Public Health Committee, replied that he would instruct the officers to report to the Public Health Committee on the present position and would bring up a report to the Council if considered necessary.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, July 3rd.—4 P.M., ANNUAL GENERAL MEETING.

HARVEIAN SOCIETY OF LONDON.
THURSDAY, July 5th.—4.30 P.M. Meeting at Guy's Hospital, St. Thomas's-street, S.E.: Demonstrations in the museum and the cardiological, bacteriological, and radiological departments.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, July 2nd, to SATURDAY, July 7th.—BROCKLEY HILL COUNTRY ORTHOPÆDIC HOSPITAL. Demonstration by Mr. G. Perkins at 11.30 A.M. on Tues., if ten post-graduates notify their intention to be present (Telephone: Mayfair 2236).—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Broad-street, W.C. Demonstration by Mr. M. L. Hine at 3 P.M. on Thurs.—CHARING CROSS HOSPITAL. Demonstration by Dr. F. G. Chandler at 2 P.M. on Fri. The above are free.—WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck-street. Special course of lectures and clinical demonstrations upon selected cases at 5 P.M. daily.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.
MONDAY, July 2nd.—2.30 to 5 P.M. Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M. Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.
WEDNESDAY, July 4th.—4 P.M., Mr. E. Pearce Gould: The Management of Inoperable Malignant Disease.

Appointments.

BOWES, GERALD K., M.D. Oxf., D.P.H., has been appointed Medical Officer of Health, Bedford.

DEARNLEY, GERTRUDE, M.D., B.S. Lond., Gynæcologist, Hornsey Central Hospital.

MCDONALD, NIEL, M.B., Ch.B. Manch., L.R.C.P. Lond., M.R.C.S., Anæsthetist to St. Peter's Hospital for Stone, Covent Garden, W.C.

ROSS-KEYT, F. D., M.B., Ch.B. Aberd., D.P.H., Medical Officer of Health for Stoke Newington.

TOOTH, R. S., L.R.C.P. Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Acts for Lewes.

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne, District Infirmary.—3rd H.S. At rate of £150.
Association of Surgeons of Gt. Britain and Ireland, 17, Wimpole-street, W.—Surgical Scholarship. £350.
Bombay, Cama and Albless Hospitals.—M.O. Rs.800–50–1000.
Bradford City.—Asst. S.M.O. £600.
Brighton, Royal Sussex County Hospital.—H.S. £150.
Bromley, West Kent Joint Hospital Board, Infectious Hospitals.—Res. M.O. £400.
Burton-on-Trent, General Infirmary.—Sen. Res. H.S. £200.
Cardiff Royal Infirmary.—Hon. S. to Ear, Nose and Throat Dept.
Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Jun. H.S. £50. Also Pathologist. £75.
Colchester, Essex County Hospital.—Asst. H.S. and Reg. £120.
Dumfries, Crichton Royal Mental Hospital.—Clinical Pathologist. £400.
Eastcote, Middlesex, St. Vincent's Orthopædic Hospital.—Res. M.O. At rate of £150.
Exminster, Devon Mental Hospital.—Jun. Asst. M.O. £300.
Gravesend, Gravesend & North Kent Hospital.—Jun. H.S. At rate of £100.
Hackney and Stoke Newington Tuberculosis Dispensary, Kingsland-road, E.—Clin. Tuberculosis Officer. £750.
Hackney Hospital, High-street, Homerton, E.—Jun. Asst. M.O.'s Each £350.
Hartlepool, Hartlepool Hospital.—H.S. £150–£200.
Hove, Lady Chichester Hospital.—H.P. At rate of £100. Also Jun. H.P. £50.
Hull, City and County of Kingston-upon-Hull, &c.—Asst. M.O.H. £600.
Kensington Tuberculosis Dispensary, 119, Ladbroke-grove, W.—Temporary Tuberculosis Officer. 35 gns. a month.
Leeds Public Dispensary.—Sen. Res. M.O. £200. Also Hon. P.
London Jewish Hospital, Stepney Green, E.—Hon. Radiologist.
London School of Hygiene & Tropical Medicine, 25, Gordon-street, W.C.—Research Studentship in Helminthology. £250.
Manchester, St. Mary's Hospitals.—4 H.S.'s. Each at rate of £50.
Manchester, Salford Royal Hospital.—H.P. At rate of £125.
Manchester University.—Reader in Materia Medica and Therapeutics. £800.
National Hospital, Queen-square, W.C.—Hon. Surg. Asst.
Newark Hospital and Dispensary.—Res. H.S. At rate of £150.
Northampton Mental Hospital, Berrywood.—Locum tenens M.O. 7 guineas weekly.
Nottingham, City Mental Hospital.—Jun. Asst. M.O. £350.
Plumstead and District Hospital, Plumstead High-street, S.E.—Second Asst. M.O. £350.
Plymouth, South Devon and East Cornwall Hospital.—Res. Surg. Officer. At rate of £100.
Preston, Biddulph Grange Orthopædic Hospital.—Jun. H.S. £150.
Reading, Royal Berkshire Hospital.—H.P. Third H.S. Also First H.S. Each £150.
Richmond, Surrey Royal Hospital.—Jun. H.S. £100.
Royal Army Medical Corps.—Commissions.
Royal Free Hospital, Gray's Inn-road, W.C.—Jun. Clin. Assts.
Royal London Ophthalmic Hospital, City-road, E.C.—Gifford Edmonds Prize in Ophthalmology. £100.
St. Mark's Hospital, &c., City-road, E.C.—Res. Surg. Officer. At rate of £150.
St. Mary's Hospital, W.—Dental Surgeon.
Sheffield, Jessop Hospital for Women.—Three Asst. H.S.'s. Each at rate of £100. Also Sen. Res. O. £250.
Surrey County Council.—Deputy County M.O.H. Also Asst. M.O. £1000 and £600 respectively.
Taunton, Taunton & Somerset Hospital.—Jun. House M.O. At rate of £100.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.P. and H.S. Both at rate of £100.
West Bromwich, Hallam Hospital.—Res. H.P. £250.
West London Hospital, Hammersmith-road, W.—Res. Asst. Surg. £200.
Wrexham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £100.
York, The Retreat.—Temporary Asst. Phys. 6 guineas weekly.

The Secretary of State for the Home Department gives notice of vacancies for Medical Referees under the Workmen's Compensation Act for the Inverness (Mainland) District (Sheriffdom of Inverness, Elgin, and Nairn), and for the Wick District (Sheriffdom of Caithness, Orkney, and Shetland). Applications should reach the Private Secretary, Scottish Office, Whitehall, London, S.W., not later than July 18th.

Births, Marriages, and Deaths.

BIRTHS.

MITCHESON.—On June 18th, the wife of George F. L. Mitcheson, B.A., M.B., B.Ch. Oxf., of Hathersage, Benfield Way, Portslade, of a daughter.

MARRIAGES.

ARMSTRONG—HOUGH.—On June 21st, at St. Margaret's Church, Streatham Hill, Dr. J. S. Armstrong to Agatha Mary, daughter of the Bishop of Woolwich and Mrs. Hough.

BEVERIDGE—MACNAMARA.—On June 12th, at the Church of the Sacred Heart, Donnybrook, Dublin, Major Arthur Beveridge, M.C., R.A.M.C., to Sheila, only daughter of Lieut.-Colonel W. J. and Mrs. Macnamara, Herbert Park, Dublin.

MILNER—MARDALL.—On June 23rd, at the Parish Church, Harpenden, Dr. J. G. Milner to Monica Thrale Mardall.

MONCRIEFF—WEDMORE.—On June 20th, at All Saints', Clevedon, Somerset, Alan Moncrieff, M.D., M.R.C.P., to Honor, only child of Mr. and Mrs. Cecil Wedmore.

DEATHS.

DREW.—On June 23rd, at Donnington-square, Newbury, Robert S. Drew, M.B., L.R.C.P., aged 50.

HANDFORD.—On June 24th, at Elmfield, Southwell, Henry Handford, M.D., F.R.C.P., aged 73.

KEATINGE.—On June 21st at his residence in Jersey, Dr. H. Pottinger Keatinge, C.M.G., late Director, Egyptian Government Medical School and Kasr-el-Ainy Hospital, Cairo, aged 67.

WILLIAMS.—At Villerville, on June 18th, Richard Tudor Williams, M.B., B.S. Lond., of Llanfairfechan and of Plas-y-Ward, Ruthin.

N.B.— A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE WORK AND RESPONSIBILITIES OF THE PATHOLOGIST.[1]

By Sir Bernard Spilsbury,
HON. PATHOLOGIST TO THE HOME OFFICE.

THE pathologist is a specialist in the study of the scientific aspects of disease, considering them from the point of view of the essential causes of disease, of the changes, visible and microscopical, which they produce in the body, and of the reactions which they provoke in the patient. Employing laboratory methods, and with the aid of instruments of precision such as the microscope, the pathologist applies his skill and knowledge to the diagnosis and the treatment of disease. The growth of scientific knowledge during the last 50 years, and the elaboration of laboratory methods of investigation, have greatly increased his labours, and they are bringing about a division of the work between the pathologist, using the term in the narrower sense, the bacteriologist, and the chemist. In this address I employ the term "pathologist" to include these three groups of workers.

The Romance of Anthrax.

I propose to give a few illustrations of the achievements of pathology in the study of the causes and processes of disease, and to indicate some of the applications of this knowledge. I will take first what I like to call the romance of anthrax. Anthrax is a very fatal disease, to which sheep, cattle, and horses are specially susceptible, men being infected directly from these animals or from their hides and wool; in this country, where the disease is a rare one, it is from imported hides and wool that the danger arises in almost all cases. The disease has been recognised from very early times; the murrain of cattle recorded in Exodus is supposed to have been anthrax. In the Middle Ages widespread epidemics were recorded in Europe and Asia, in which cattle and sheep were decimated, and anthrax has been one of the factors in the production of famines. About the year 1850, tiny bodies were observed under the microscope in the blood of animals suffering from the disease, and it was claimed that blood containing these bodies produced the disease when it was introduced into a healthy animal. The matter was still under dispute when, in 1876, Koch, at that time a country practitioner in Germany, devised methods of growing the organism outside the body in tubes of culture media; he showed that these cultures had distinctive characters, and he reproduced the disease in healthy animals by injections of the cultures, obtaining the same organisms again from the experimental animals when they succumbed to the infection. Koch's discoveries of the organisms of tuberculosis and of cholera came later, and the application of his methods by other workers has resulted in very notable discoveries of the causative agents in disease, but it was his discovery of the cause of anthrax which was utilised by Pasteur—who had already begun his investigations on infectious diseases—to develop a method of protecting animals against disease. Starting from the known fact that an animal which had recovered from an attack of anthrax was protected against the infection, he experimented with cultures of the anthrax bacillus until he succeeded in so reducing the virulence or potentiality to reproduce the disease, that after injection of the attenuated cultures into healthy animals these developed protective powers which enabled them to resist the subsequent injection of virulent cultures of the organism. The method of protective inoculation has been widely employed in countries where the disease is prevalent, with the result that the mortality in cattle and sheep has been greatly reduced. In France, for example, where millions of inoculations are made in the course of the year, the death-rate in animals has been reduced to about one-twentieth of what it was before inoculation methods were employed.

Rabies.

The success of this method led Pasteur to attack hydrophobia, of which the mortality in dog and man was very high. He did a considerable amount of experimental work on animals, and he showed that rabbits could be infected from rabid dogs and from patients who had died from the disease. He found that the virus or active principle of the disease was always present in the spinal cord of the rabbits used in experiments, and that healthy dogs could readily be infected by injections made from this material. On keeping the spinal cords of the rabbits under carefully controlled conditions he found that the virus rapidly lost its strength, until at length it failed to reproduce the disease in dogs. Taking advantage of the fact that persons bitten by rabid dogs usually did not develop the disease for some weeks, he injected into patients preparations from the spinal cord of the experimental rabbits, using first a very attenuated virus, and repeating the injections with viruses of increasing virulence. By that means he succeeded in protecting the patient before the natural disease had time to develop. The result of this treatment, carried out in the Pasteur Institutes in different parts of the world, has been to reduce the fatalities to less than 1 per cent. of those treated.

I have described the investigation of anthrax and hydrophobia, because they are pioneer examples of the pathological methods used in the discovery of the cause and the treatment of infectious disease. In some infections the protective powers conferred upon the patient or the animal are present in the blood, and advantage is taken of this fact to treat patients who are suffering from one of them by injections of serum from an animal which has been protected or immunised against that particular infection. The animal used for this purpose receives a number of injections, containing the organism or its specific poison, in carefully graduated doses. After each injection substances are developed in its body and blood, which counteract the effects of the poison which has been injected; after a number of injections the protection conferred upon the animal is a very high one. A part of its blood is then withdrawn from the animal, and from it is separated the serum which is used for injection into the patient, where it acts as an immediate antidote to the poison produced by the disease. One of the most frequent applications of serum treatment is in diphtheria, and it has been clearly proved that the mortality from the disease is greatly reduced by the injection of the specific serum; the beneficial effects are very striking when the patient is treated at an early stage of the illness, but every day's delay in the use of the serum diminishes its efficacy.

Diphtheria.

The pathologist, as part of his routine work, is asked to diagnose infectious disease by the discovery of the organism. In many cases this is accomplished by microscopical examination, aided by the examination of cultures made from tissue or body fluids of the patient. In some cases these methods fail, and recourse may be had to animal experiments to enable the diagnosis of the disease to be obtained. A disease in which such investigation is often required is tuberculosis, for in obscure and early cases the search for the organism by microscopical methods may be hopeless. An injection of the suspected material is made into a guinea-pig, and after allowing sufficient time for the disease to develop, the animal is killed. The changes produced by the tubercle bacillus are characteristic, and the presence of these changes in the dead body of the animal enable a diagnosis to be made in many cases where other methods have failed. Another difficulty with which the pathologist has to contend is that some of the bacteria which produce specific diseases have their doubles—i.e., organisms which are exactly like them in appearance and it may be also in the growth of cultures made from them, but which are themselves harmless, and sometimes the two organisms can only be distinguished by means of animal experiments. I recall in that connexion the case of a schoolboy who developed diphtheria, and from whom I obtained the organism of the disease. The boy made a good recovery, and as a precaution he was examined again to be certain that no diphtheria organisms were still present in his throat which might render him a danger to others. I found the organism in small numbers; the treatment was continued and the boy kept in isolation. Repeated bacteriological examination, extending over more than two months, always showed the presence of a few organisms. At last it was decided to inject the organisms into a guinea-pig. This was done, and the animal suffered no ill-effects, as it would have done if the organism had been an active diphtheria bacillus; it was thus proved that the boy had got rid of the diphtheritic infection, and was harbouring its harmless double.

There is much misunderstanding of the nature and effects of inoculation experiments upon animals. In the vast majority of cases the animal suffers no worse effect, at the time of introduction of the material, than the prick of a hypodermic needle. In some cases the development of the disease quickly ends in death; in others, as for example tuberculosis, the animal presently shows signs of the disease sufficient to indicate that it should be destroyed and its dead body examined. Such an animal suffers far less than the patient in whom the disease would terminate fatally. It is only in a very small proportion of cases that serious suffering, in the sense of pain, attends inoculation experiments, and in these cases it is usually short-lived owing to the rapid progress of the disease.

[1] The Stephen Paget Memorial Lecture delivered on June 19th to a meeting of the Research Defence Society.

Chemical Problems.

Many chemical problems are presented to the pathologist. Shortly after the outbreak of war I was asked by a London coroner to make a post-mortem examination of a man who had died from jaundice. The man had been working at one of the newly established aeroplane works at Hendon, in a building in which the wings of the aeroplane were constructed and varnished, and he was exposed to the heavy fumes of the varnish or "dope" given off from the wings after the varnish had been applied. Other workers in the building had suffered, but less severely, and it was suspected by the workers that the fumes of the dope were responsible for their ill-health. My examination of this man showed that his death was due to severe disease of the liver, similar in some respects to a rare form of severe jaundice, but differing in certain particulars; the presence of this disease, and the fact that other workers were suffering in a similar manner, strengthened the suspicion that some form of poison was responsible for the illness. My colleague, Sir William Willcox, who had examined the man during his illness, was called in, and was furnished with samples of the dope and of its separate ingredients, which included methylated spirit, acetone, benzine, and tetrachlorethane. These substances were all present in the vapour given off by the varnish as it dried, and it was a matter of considerable importance to determine which, if any, of these substances acted as a poison. This could only be done by experiments on animals, and a number of rats were exposed to the action of the fumes for some hours daily for about a week. One rat was subjected to the vapour given off by the varnish itself, and others to that of the four volatile ingredients separately. It was proved during the experiments that the animals exposed to the varnish and to tetrachlorethane suffered in health, being drowsy, taking less food, and not increasing in weight like the other animals. At the end of a week the animals were killed, and their organs were examined microscopically, and it was found that the effect of tetrachlorethane had been to produce severe damage to the liver, dope itself producing less severe damage, whilst the other three ingredients of the dope produced no ill-effects. By this means information was obtained as to the cause of the illness, which could not have been gained in any other way. The result of the investigations was that improved ventilation systems suitable to this form of vapour were introduced into the factories, since the work was urgent and could not be stopped; the workers were subjected to regular medical inspection; later it was found possible to substitute a non-poisonous medium for the poison tetrachlorethane. In all, some 70 persons suffered severely, and 12 died, most of the illnesses having been contracted before the cause had been ascertained; by this means poisoning by tetrachlorethane eventually ceased, no case occurring during the later years of the war.

Another poison on which investigation was required during the war was trinitrotoluene, more familiarly known as T.N.T. Here the problem was a different one, because the substance is a pure chemical and is a solid and not a vapour; the question in cases of illness was as to the portal by which the poison entered the system. Here, again, experimental work served a very useful purpose in indicating the measures to be employed to reduce the risk of handling the substance. Another chemical poison is carbon monoxide, the poisonous constituent of coal-gas and a product of incomplete combustion. In this case the experiments on mice, carried out by Prof. J. S. Haldane, established the mechanism by which the poisonous action was produced, and demonstrated the proper method of treating those who were suffering from its effects.

Conclusion.

In this inadequate survey of the work of the pathologist I have continually directed attention to the use of experiments upon animals, both in the study of the origins of disease and as an aid in diagnosis and treatment. A large part of our knowledge of bacteriology is based upon experimental work; this is inevitable in the present state of our knowledge, for an important means of testing suspected organisms is by the reproduction of the disease in living animals. It is also required for the diagnosis of infectious disease in the patient, and pathologists are finding themselves compelled to have a Home Office licence for vivisection, in order to perform the necessary tests on living animals. For this reason, in recent years, the number of licences granted to pathologists all over the country has greatly increased. With regard to the responsibilities of the pathologist, he is a medical practitioner, who, like his clinical colleague, has to apply his skill and knowledge to the best advantage for his patients. He must avoid error as far as possible, employing exact methods, which must include, at present, animal experiments. The scientific advances of the last 50 years in relationship to medicine have been largely based on experimental work, and have gone far to revolutionise the treatment of some diseases; as a result there are infections, which at one time were widespread, with which the modern practitioner is scarcely acquainted. If our forbears of a century ago could see the work which has been done in modern science and medicine, they would exclaim: "Had we but had your knowledge, what an enormous amount of suffering would have been prevented."

THE TELEPHONE SERVICE AND THE VILLAGE NURSE.

THE question was recently brought up in the House of Commons as to whether, in the interests of her patients, the installation of a telephone in the home of the village nurse is so desirable that special concessions ought to be offered in order to induce her to procure one. Mrs. Runciman and Commander Bellairs suggested that she should be allowed to rent the telephone at the quarterly rate payable by the private subscriber (£1 7*s.* 6*d.*) instead of that (£1 15*s.*) payable by one who uses the instrument substantially for professional purposes. Lord Sandon went even further in asking the Postmaster-General whether he would take steps to see that all district nurses in rural areas should have a telephone installation. The reply was not encouraging. Lord Wolmer, Assistant Postmaster-General, pointed out that difficulties might arise if the Post Office attempted to discriminate between groups of professional people and offered the same service to any one class of subscribers at a lower rate than that charged to others. If nurses were granted such a privilege doctors and chemists might feel aggrieved. In our view there is some justification for differentiation in favour of the doctor, the chemist, and the nurse, as against other professions, since it is in the public interest that their services should be available at short notice. It seems unlikely, however, that the Post Office will consent to their exemption from the extra payment demanded from professional subscribers. As far as the village nurse is concerned, it seems to us doubtful whether the routine installation of a telephone, under the present conditions of the service in villages, would be of great value, even if she lives with other people who are willing to take down messages. As a rule she lives in a cottage which is empty when she is at work, that is for most of the day, and between 8 P.M. and 8 A.M., when she is likely to be at home, the telephone service in many villages is not open. Those interested in rural medical and nursing needs of villages might with more advantage press the Post Office to arrange for a night service throughout the kingdom. This seems to us a really important step towards ensuring prompt attention for the sick, and when it has been achieved the village nursing associations will probably find it expedient to install and maintain a telephone in the nurse's home out of general funds at their disposal.

A SAFETY BATHING COSTUME.

WE have received from the Institute of Patentees, Roxburghe House, 273–287, Regent-street, London, specimens of the "Swimeezi" bathing costumes, which have been designed by Dr. M. W. Browdy as an effort to overcome the numerous calamities which occur each year through beach bathing. These costumes look outwardly like ordinary costumes, but the portions covering the chest and the back are constructed as rubber air-chambers, designed to be maintained in a definite anatomical position when inflated. The greater area of buoyancy given to the front of the garment is intended to cause the bather to roll on his back should he be in difficulty. The rubber air-chambers can be inflated or deflated easily by a neat valve construction, and swimming experts who have tested the invention speak highly of it.

VITAL CAPACITY OF NEGROES.

Dr. W. G. Smillie and Dr. D. L. Augustine have been investigating hookworm in a group of about 2000 white and negro school-children in South Alabama.[1] As a by-product of this study they have measured the vital capacity of about 1000 persons, and have found that the results for the white people corresponded closely to the standard tables of Myers. The negroes, however, showed in all the groups studied a consistently and markedly lower vital capacity than the whites. The discrepancy was partly explained by measurements of the sitting height, for the negroes tend to have a shorter trunk length than the whites. Even after correction for this, however, the vital capacity is more than 15 per cent. lower. Disease cannot have played any great part in producing this figure, for the men were picked for their strength and ability to do hard work. The investigators believe, therefore, that low vital capacity is a racial characteristic. It is tempting to correlate this with the black man's well-known susceptibility to respiratory diseases, but of course the assumption is at present without foundation.

SOCIETIES, MEDICAL.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—Basal metabolism in clinical medicine, 814
BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—Blandy, Mary, trial of, 291; gastric ulcer, 83; myopia in childhood, 1014; radium rôle of, in cancer of breast and tongue, 554
BUXTON MEDICAL RESEARCH SOCIETY.—Auricular fibrillation, treatment of, 657
CALEDONIAN MEDICAL SOCIETY.—Jubilee celebrations, 376
CAMBRIDGE MEDICAL SOCIETY.—Demonstrations and cases, 236; varicose veins, treatment of, by injection, 236
EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—Anæsthesia in high abdomen operations, 397; fæces, unrecognised toxic substances in human, 174, 236; forceps delivery, reduction of, as basis for prophylactic gynæcology, 450; pneumonia in childhood, clinical and pathological demonstration, 397
EDINBURGH OBSTETRICAL SOCIETY.—Ovulation and the menstrual cycle, 658; puerperal hæmorrhage, three cases of, 292; puerperal sepsis, maternal mortality from, 1178; vulvo-vaginitis, 291
FEDERATION OF MEDICAL AND ALLIED SERVICES.—Council of Industrial Medicine, meeting of, 497
HARVEIAN SOCIETY OF LONDON.—Buckston Browne prize, subject for, 375; clinical meeting, 529; colitis, ulcerative, treatment of, discussion on, 857; toxicology and its application to medical practice, 603
HUNTERIAN SOCIETY.—Hiccup, discussion on, 604; Hunterian bicentenary: conversazione, 424; festival dinner, 367; Hunterian oration by Dr. Anthony Feiling, 449, by Dr. Howard Kelly, 134; programme, 57
JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.—Colon, carcinoma as applied to the, 58
LIVERPOOL MEDICAL INSTITUTION.—Diverticulitis, surgical treatment of, 396; fracture reduction, ritual of, 80; presidential address, 164; rheumatism in childhood, detection and cure of, 190; statistics, 190
MANCHESTER MEDICAL SOCIETY.—Arthritis, chronic, ætiology of, discussion on, 395; colloidal lead, 706; gastric and duodenal ulcers, series of 183 consecutive cases, 706; ophthalmology in relation to general medicine, 83
MANCHESTER PATHOLOGICAL SOCIETY.—Annual meeting, 1073; blood pressure, high, 396; breast, normal, and abnormal states of connective tissue of, 707
MEDICAL SOCIETY OF LONDON.—Cancer of cervix, treatment of, discussion on, 652; carrier problem, the, 553; dinner, 633; pernicious anæmia, treatment of, discussion on, 185; programme of spring session, 58; ultra-violet light therapy, use and abuse of, discussion on, 392
MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.—Antenatal treatment of gonorrhœa, discussion on, 757; antenatal treatment of syphilis, discussion on, 232; gonorrhœa in pregnancy and the puerperium, 501; Kahn reaction, clinical aspects of, 971; syphilis, relation of, to malignant changes, 1013
MEDICAL WOMEN'S FEDERATION.—Gastric secretion and other digestive factors in rosacea, 290; radium treatment of uterine cancer, 759
MEDICO-LEGAL SOCIETY.—Drunkenness and civil and criminal responsibility: a study in comparative law, 235; pain in its medico-legal aspects, 656; parturition, influence of, upon insanity and crime, discussion on, 379, 447

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—Anus, imperforate, 1177; cancer of cervix, cystoscopy in, 759; exhibition of cases and specimens, 340, 605; hæmatometra associated with tuberculosis, three cases of, 82; hydrops tubæ profluens, 82; isthmial pregnancy, ruptured, 82; placenta accreta, case of, 1177; vulva, pseudo-elephantiasis of, 82; Wertheim's hysterectomy, value of drainage in, 1177

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—Asthma syndrome, pathological mechanism of the, 288

OPHTHALMOLOGICAL SOCIETY.—Annual congress, proceedings at, 859, 967

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—Meeting, 80

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Bone pegs, 81; bronchiectasis, a case of, 238; fracture, ununited, 82; obstetric practice at the Rotunda, 969; Pepys, medical references in, 680; psychoneurosis, a case of, 237; sensitive child, the, 237; spinal caries, 81; sternum, typhoid infection of, 81; vitamin-A deficiency in Newfoundland, 969

ROYAL INSTITUTE OF PUBLIC HEALTH.—Abortion, criminal, 551; Insane and mentally defective, present state of the care of, 515; Medical practitioner in relation to the administration of justice, 183; programme of lectures, 57; Psychiatry, forensic, problems in, 394; Whitsuntide visit to Paris, Aix, and Vichy, 1342

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.—Annual meeting, 1360; cardiac disease, mental state in, 501; globus pallidus, histology of the, 500; meeting, 318, 500; psychiatry, the new, 1074

ROYAL SOCIETY OF MEDICINE.—Achalasia and degeneration of Auerbach's plexus, 1174; alcoholism, ætiology of, discussion on, 704; anæmia, aplastic, 1123; anæsthesia in obstetrics, discussion on, 498; appendicitis in children, chronic, discussion on, 444, 595; carbon dioxide thermo-saline springs, 546; cardiac infarction, discussion on, 188; diathermy in relation to circulatory disturbances, discussion on, 187; dysmenorrhœa from calcification of ovary, 1282; dysphagia due to pharyngeal paralysis, 1174; ear, internal, vasomotor affections of, 1176; eclampsia, standard of results in the treatment of, 1281; encephalitis lethargica, later phases of, discussion on, 912; ocular complications of, discussion on, 339; fractures, operative treatment of recent, discussion on, 808; hæmorrhage, post-operative, 1174; hare lip, 1227; influenza ear, the, 1177; kidney, rôle of, in non-renal disorders, 911; larynx, intrinsic cancer of, operated through a laryngo-fissure, 1175; lysozyme, the antibacterial body, 1228; middle-ear disease, effects of on efficiency in civil and military life, discussion on, 812; narcolepsy, discussion on, 550; naso-oral sepsis, influence of, on lungs and gastro-intestinal tract, discussion on, 130; naso-pharyngeal epidemics in public schools, 1329; osteomyelitis, acute, treatment of, 499; otosclerosis, pathology of, 1176, a working hypothesis for research in, 1175; programme, 57; radium therapy, present position of, 602; reception at, 132; rectum and colon, early diagnosis of cancer of, discussion on, 1124; rheumatism, juvenile, some public health aspects of, 446; sinusitis, familial infectivity of chronic, 1175; tooth, the pulpless, discussion on, 654; tracheotomy, silent, signification of, 1175; typhoid fever in the Royal Navy, epidemiology of, 393; varicose ulcers, treatment of, by injection of sclerosing solutions, discussion on, 1073; visit of surgical section to Canada and the United States, 309; vulval metastases from pelvic growths, 1283; widening of scope of, 943

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—Dinner, 1348

SOCIETY OF BRITISH NEUROLOGICAL SURGEONS.—Meeting, 133

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Diphtheria, control of, in institutions, discussion on, 965; food, recent advances in knowledge of, discussion on, 184; programme, 58, 214; tuberculosis mortality, causes of decline in, discussion on, 858

TUBERCULOSIS SOCIETY.—Care committees and kindred agencies, work and aims of, discussion on, 233

ULSTER MEDICAL SOCIETY.—Annual general meeting, 1155

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—Cardiac murmurs, functional, origin and diagnosis of, 341

WOLVERHAMPTON AND DISTRICT CLINICAL CLUB.—First general meeting, 680

Society of Apothecaries of London, Diplomas granted, 679, 1205, 1359, livery dinner, 58; pass-lists, 267, 478, 679, 942, 1205, 1359

THE CONDUCT OF MEDICAL PRACTICE

BY

THE EDITOR OF "THE LANCET" and Expert Collaborators

The book is a guide to the conduct of medical practice in all its shapes. It deals with the medical career generally—with the circumstances which should influence the student's decision to adopt one or other of its branches, and with the various situations in which the medical practitioner is placed, both in the establishment of himself in a practice and in carrying it on with regard for his public obligations and his professional responsibilities.

Demy 8vo. *Cloth.* 348 *pp.* *Price* 10/6 *net* (*postage 6d. extra*).

Valentine's Meat-Juice

For **Quieting** the **Irritable Stomach** in **Pregnancy**, for **Rapidly Restoring** the **Vital Forces** in **Hemorrhage**, for **Sustaining** and **Strengthening** in **Long** and **Exhausting Labor**, **Valentine's Meat-Juice** is Extensively employed in

Obstetrical Practice.

Dr. M. DeCristoforis, *Prof. Lecturer on Midwifery and Gynæcology, Milan, Italy:* "The preparation, VALENTINE'S MEAT-JUICE, has been successfully used by me in a serious case of acute puerperal hemorrhage. The patient could take no food or drink. VALENTINE'S MEAT-JUICE was completely retained and restored very promptly the strength and the cardiac impulsion."

Dr. E. Duloroy, *Physician Accoucheur to the International Hospital, Paris, France:* "A young accouchée, in a very weak condition and suffering from stomach trouble, could retain no food, but was able to assimilate VALENTINE'S MEAT-JUICE given at first in small doses. An improvement was quickly visible, the patient recovered her strength and is today in good health."

VALENTINE'S PREPARATION
NUTRIO PER ME
VOLUME 1 4/5 OZ.
MEAT JUICE
The result of an Original Process of preparing Meat and extracting its Juice by which the elements of nutrition are obtained in a State ready for immediate absorption.
DIRECTIONS. Dissolve one teaspoonful of the Preparation in three tablespoonfuls of cold or warm water. Boiling water changes the character of the preparation

For Sale by European and American Chemists and Druggists.

The Methods of Clinical Diagnosis

By **A. G. GIBSON,** M.D., F.R.C.P., Lecturer in Morbid Anatomy in the University of Oxford, and **W. T. COLLIER,** M.D., M.R.C.P., Honorary Assistant Physician to the Radcliffe Infirmary, Oxford.

From the BRITISH MEDICAL JOURNAL REVIEW:—

"In choosing the volumes which are to form his own intimate library, it is of the utmost importance for the student and the recently qualified man to include at least one of those handy little books which deal with the bedrock elements of professional knowledge. In extending a hearty welcome to the latest of these, it is safe to predict for it a speedy popularity. The book is packed with useful information presented in a lucid and interesting manner. . . . . It is surprising what a wealth of useful information the authors have compressed within 398 pages, and that they have done so in such a readable manner is proof that they have accomplished what they set out to perform. The printing is clear and the diagrams adequate. A work such as this will be constantly referred to not only by the student but by the man in busy practice."

HEALTH SERVICES AND THE PUBLIC

By

STELLA CHURCHILL

M.R.C.S., L.R.C.P., D.P.H., L.C.C.

Good health is as important to the nation as good food, yet how many know what health services are available, which are free, which are not, and what these cost. The author describes the free services and shows where they break down and why. She makes a vigorous appeal for the reorganisation of the nation's life.

HOLVIGLASS

HOLVIGLASS INDISPENSABLE IN SUNLIGHT THERAPY

Whether you practise actino-therapy by means of direct sunlight or the arc lamp, Holviglass "the supreme ultra-violet ray glass," is essential for your purpose.

Holviglass has been proved by the severest tests to transmit the maximum amount of useful ultra-violet rays, both artificial and sunlight.

Lamps fitted with Holviglass are the most satisfactory and efficient, as Holviglass does not crack or become in any way impaired through the action of heat.

Holviglass is the strongest and most durable ultra-violet ray glass obtainable.

Holviglass is highly resistant to film and therefore easiest to keep clean. It is practically colourless, having indeed less colour than ordinary window-glass.

INTERESTING BROCHURE FREE

An interesting brochure entitled "The Light that is Life," giving a brief and lucid description of Holviglass and some details of tests carried out in the Glass Technology Department of Sheffield University, and in the Holophane Laboratories, will be sent free on application. Address to—

Artificial ALPINE SUN
The standard outfit for general practice.
D.C. model, **£22 10 0**
A.C. model, **£38 0 0**

The benefits of actino-therapy are becoming generally realised by the public as they have been by the medical profession. It is of first importance that the practitioner should be able to meet his patients with the necessary resources for ultra-violet treatment. A Hanovia Quartz Lamp in the consulting room enables the practitioner not merely to prescribe but himself to administer treatment in remarkably varied cases and with the best results. The New Hanovia Home-Sun Quartz Lamp can be used or installed at the patient's bedside.

The fact that over 100,000 Hanovia Lamps are in daily use all over the World is sufficient evidence of their recognition by foremost medical authorities.

Hanovia apparatus is individually tested, and carries a twelve months' guarantee. Hanovia service to users includes the monthly issue of an informative periodical, "The Quartz Lamp," free of charge. Technical advice is always available without obligation or cost from an Hanovia representative.

THEN — AND NOW

There is in London a Radiological collection showing the evolution of the X-ray Tube.

This exhibit, which includes one of Röntgen's early tubes, demonstrates the various stages of development and concludes with the "METALIX."

In most walks of life the same progressive changes are evident, and in the "METALIX" tube are embodied the results of careful research and an exact knowledge of the Radiologist's requirements.

See the Tube in use in any large Hospital

The "METALIX" gives complete protection

Weighs only 6 lbs.

SCIENCE

once more endorses

HOVIS

Irrefutable Evidence

Scientific Research into the essential factors underlying the bread question has brought to light certain facts of the highest practical value to medical men as well as to the general public.

Hovis is shown, from an analysis of many experiments, not only to possess a larger content of the growth-producing Vitamin B than other breads, but provides more positive nourishment for the quantity consumed.

One slice of Hovis weighing 1 oz. contains as much Vitamin as 2 oz. of wholemeal or 5–6 g. of fresh yeast; white bread contains only about 2 per cent. of yeast.

It is also found that "brownness" of bread is no measure of the Vitamin content.

The Wheat Germ
the secret of Hovis Nutrition

By blending patent flour with 25 per cent. wheat germ, Hovis combines the goodness of the one with the Vitamin B of the other, the vital element for healthy development. Further, containing no bran, it is very easily digested.

These facts all point to one conclusion, that in dietetic value Hovis holds the first place for promoting health.

ARTERIO-SCLEROSIS
and
HIGH ARTERIAL TENSION

Phyllosan, a chlorophyll preparation by Prof. Buergi, of Berne University, has been found most valuable in cases of cardiac weakness where other treatments gave practically no results. The action of Phyllosan was closely observed throughout a series of cardiac cases in which the heart muscle has been impaired by arterio-sclerosis and other complaints. Reports (1), (2) show Phyllosan to exert a rapid influence in restoring to normal and strengthening the cardiac action, with a decided and immediate lowering of abnormally high blood pressure.

PHYLLOSAN

may be prescribed in the usual way and will be dispensed by chemists accordingly. It is supplied in tablet form of 2·5 grs. each, packed in bottles.

(1) Rentz, Eduard (University of Upsala), "Some Investigations into the Pharmacological Properties of Chlorophyll."

(2) Buergi (Berne University) Therapeut Monatch N 42—Deuts Med. Wochen No. 35, Schweiz Rundschur No. 19.

DOSAGE.—Adults: 2 to 3 tablets three times daily before meals. Children: 1 to 2 tablets three times daily before meals.

Copies of clinical reports and medical extracts, together with samples of Phyllosan, will be sent to any member of the medical profession, free on application, from the Agents:

"HEART DEATHS"

This is the expressive term used by A. W. Meyer to denote those fatalities which occur under emergencies, such as surgical operations, labour, acute illness, etc., because of existing disorders of the heart,—asthenia, vagotonia, myocarditis, arrhythmia, and above all, exophthalmic goitre.

Many of these cases of heart death can be prevented by the timely and judicious administration of ANASARCIN.

It may also prevent post-operative thrombosis, embolism, and pneumonia.

GUARD WELL THE HEART

With all the precautions that you take to prepare your patient for these stressful emergencies, DO NOT OMIT ADEQUATE PREPARATION OF THE HEART.

ANASARCIN measures up to all the requirements of modern cardiology as a true physiologic heart tonic,—scientific in principle and effective in action.

We ask only the opportunity to prove to you its virtues in your own practice. Write us for booklet, "ANASARCIN IN DISORDERS OF THE HEART AND VASCULAR SYSTEM," and for a sample quantity to try it out.

BRESTOL is now obtainable of all Chemists.

Hunyadi János

The famous Natural Aperient Water.

Hunyadi János was introduced into this country more than sixty years ago.

It has long been recognised as the most valuable of the **Natural** Waters of the Sulphate class and infinitely superior to any combination of salts made by pharmaceutical processes, in consequence of which a very large demand has arisen for this reliable Natural Aperient. Although its composition is strong (it contains almost equal proportions of sulphate of soda and sulphate of magnesia) it is pleasant in taste and gentle in action.

Samples forwarded free to Members of the Medical Profession upon application to the Sole Agents, Ingram & Royle, Ltd., Bangor Wharf, 45, Belvedere Road, London, S.E.1.

Pituitary Extract B.D.H.

(Posterior Lobe)

On the introduction of the Therapeutic Substances Act PITUITARY (Posterior Lobe) EXTRACT was required to conform in activity to a standard laid down by the Act. No change in the B.D.H. product was necessitated, as it already conformed with the official requirements.

Further, in addition to the above-mentioned standardisation, a blood-pressure test is made on every batch of PITUITARY (Posterior Lobe) EXTRACT B.D.H. before issue.

In consequence of the care expended in its manufacture, and of the accuracy of the methods employed in its standardisation, PITUITARY (Posterior Lobe) EXTRACT B.D.H. is so uniform in its activity that physicians using it regularly know exactly the amount necessary to produce a desired reaction.

When PITUITARY (Posterior Lobe) EXTRACT B.D.H. is employed, it need not be feared that disappointing results due to comparative ineffectiveness, or annoyance arising from excessive activity of the product, will arise. In fact, the reliability of the B.D.H. product inspires and justifies confidence.

THE FRENCH NATURAL MINERAL WATER

VICHY-CÉLESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE.)

FERMENTATIVE DYSPEPSIA.

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Célestins,** by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ÉTAT" and the name of the SOLE AGENTS:—

INGRAM & ROYLE, Limited,

Bangor Wharf, 45, Belvedere Road - - - London, S.E. 1.
And at LIVERPOOL and BRISTOL.

ALOCOL

Colloidal Hydroxide of Aluminium

Successful Treatment of Hyperchlorhydria

"Alocol" is a triumph of colloidal therapy because it is completely free from the marked disadvantages associated with the usual alkaline medicaments.

Take bicarbonate of soda as an example. When in the stomach it is transformed into sodium chloride—the very product which goes to the formation of hydrochloric acid. To combat hyperacidity by such means is to create a vicious circle.

Note the different action of "Alocol." It absorbs excess of hydrochloric acid and the acid-containing mass is finally evacuated from the lower bowel. This colloido-chemical absorption removes from the system the causative acid radicle (Cl) instead of merely neutralising it.

"Alocol" thus prevents reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

"Alocol" leaves intact the acid reaction of the gastric juice and its normal digestive and bactericidal functions. It is the remedy *par excellence* for hyperchlorhydria. The absorbent, healing and sedative properties of "Alocol" also prove of the greatest value in successful treatment of the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, infective enteritis, &c.

Complete chemical history of "Alocol" with convincing clinical reports, and supply for trial, sent free to physicians on request.

INSULIN 'A.B.'

TRADE A B MARK **Brand**

INSULIN 'A.B.' Brand is prepared only in the form of sterile solution which is immediately ready for injection.

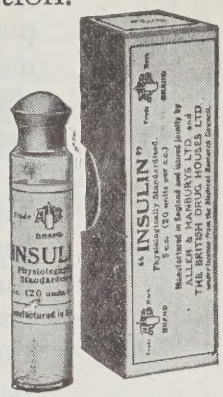
Its use ensures :
1. Ready adjustability and accuracy of dose ;
2. Full activity and stability ;
3. Absence of reaction and pain on injection.

'A.B.' Brand Insulin maintains a world-standard of purity and excellence ; its activity is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.

Supplied in Two Strengths :

20 units per c.c. Packed in bottles containing :
5 c.c. (100 units or 10 doses) **2/8** each
10 c.c. (200 „ 20 „) **5/4** „
25 c.c. (500 „ 50 „) **13/4** „

40 units per c.c. Packed in bottles containing :
5 c.c. (200 units or 20 doses) **5/4** each



Full particulars and the latest literature will be sent post free to Members of the Medical Profession :

Anusol Haemorrhoidal Suppositories

Harmless — Reliable — Quick Acting

Anusol-Goedecke affords prompt relief from pain. Anusol-Goedecke disinfects and soothes inflamed congested areas and promotes healing. One Suppository to be used night and morning.

Genuine Anusol Suppositories are issued only in red boxes closed with a cord and metal seal.

Each box contains 10 Suppositories.

Veganin

Cod. Phosph: 0.01 gram. Phenacetin: Acid Acetyl. Salicyl: aa 0.25 gram.

Neuralgia, Rheumatism, Influenza

All kinds of Headache. Painful Menstruation. Dysmenorrhoea. Tabetic Crises.

Veganin is an excellent example of the enhanced action of certain medicaments when administered in combination in a suitable form. Is markedly effective in really serious cases.

Dose. For severe irritating cough or intense pain, two tablets 3 or 4 times a day. In other cases one tablet about every four hours.

Original Tubes 10 or 20 Tablets 7½ grains.

Targesin

A Colloidal complex of Diacetyltannin—silver albumen, containing 6% metallic silver.

Antigonorrhoic

Highly effective — Non-irritant

Advantages of Targesin : Fixation and storage in mucous membrane. Penetration into Littre's Glands. Rapid cessation of secretion. Being absolutely painless, and non-irritant, it prevents complications. Strongly Bactericidal. Pronounced antiphlogistic and "deep" action. Dissolves easily and completely in water.

Application : Acute and Chronic Gonorrhoea, 1-5% Solution ; Posterior Urethritis and Cystitis, 0.2-1% ; Abortive treatment, 5-10%.

You Can Trust Your Own Judgment

OBSERVE the character and composition of Agarol Brand Compound, consider the purpose and proportions of each of its constituents; *then* try it in some case of chronic constipation that has failed to respond to other lines of treatment—*and note the results!*

The remarkable welcome Agarol Brand Compound has received from physicians the country over, and the extent to which it has superseded ordinary laxative measures, tells in no uncertain way what their judgment has been — how trustworthy they have found it.

AGAROL Brand Compound, the *otiginal* Mineral Oil—Agar-Agar Emulsion, has these special advantages:

Perfect emulsification; stability; pleasant taste without artificial flavouring.

Freedom from sugar, alkalies and alcohol; no contra-indications; no oil leakage.

No griping or pain; no nausea or gastric disturbances; not habit forming.

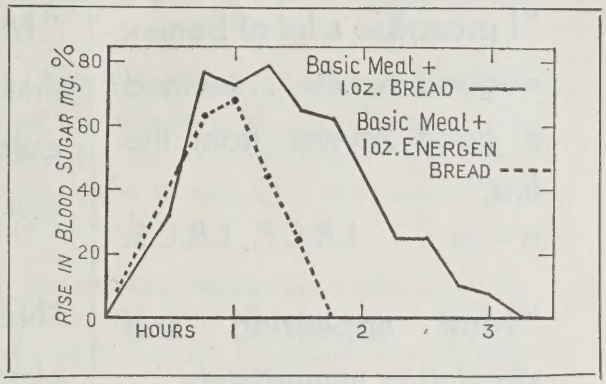
The Triumph of Energen Bread

Effect on the Blood-Sugar Rise in DIABETES.

CHART PREPARED BY HIGH AUTHORITY

(See LANCET, p. 1336, Vol. II., Dec. 24th, 1927.)

Shows rise in blood-sugar after the test-meal plus 1 oz. bread and after the same meal plus 1 oz. Energen bread.
The area between the curve and the base-line represents the total rise. The base-line represents the initial fasting blood-sugar.



According to LANCET *analysis Energen Bread contains* 15 % *less carbohydrate than the average analysis made by Joslin of ordinary wheat breads*

A FULL report of an investigation to determine the effect of Carbohydrate Foodstuffs on the blood-sugar in Diabetes was published in "The Lancet" of Dec. 24th, 1927.

This report shows that Energen Bread gave in three experiments on one subject, a rise in blood-sugar of about half that of the Hospital bread used, and is conclusive evidence that ordinary Bread, however high the quality, is unsuitable for the diabetic diet.

Energen Bread contains standardised and unvarying proportions of Protein, Carbohydrate and Fat. It is prescribed by leading physicians and is in use at the principal Hospitals. It is the only diabetic Bread which should be prescribed to ensure the best results.

During the Insulin treatment Energen Bread is invaluable as it gives complete control of the essential carbohydrate intake.

Physicians are invited to send for tables of gram and calorie values, and full analyses of all Energen Starch-Reduced Foods, together with samples of Energen Bread for complete test diets without charge.

PRICE FROM 1/3 PER BOX

Note for the Medical Profession

Selective Germicidal Power

IT is not generally recognized that antiseptics exhibit wide variations in their power of killing different bacteria. Any given antiseptic may kill one organism under certain conditions in high dilution; for another organism under similar conditions it will be found comparatively innocuous.

Phenol, the first antiseptic ever used, affords an example of this. It differentiates so markedly between the typhoid-coli group and the Gram-positive cocci that, if added in the proportion of 1 in 200 to a medium inoculated with a mixture of B. coli and streptococci, the former are killed and the latter multiply.

This poverty of action on the Gram-positive cocci—the common causes of sepsis—is characteristic not only of phenol, but of most of the powerful coal-tar antiseptics on the market, their active constituents being chemically allied to phenol.

Monsol, which is derived from a by-product of the Mond power-gas process, differs radically from other coal-tar antiseptics in its selective action. Its power of killing the Streptococcus Pyogenes is *more than* 10 *times greater than that of pure phenol or of lysol.*

Monsol is non-poisonous and non-irritant, and can be applied in effective dilution even to mucous membranes. In view of these facts, it is not surprising that Monsol has been found to have unprecedented qualities in the treatment of streptococcal infections.

Monsol can be applied to the treatment of septic conditions of the SKIN, the MOUTH and THROAT, and the GENITO-URINARY TRACT.

'ULTRATAN'
The LONDON HOSPITAL BINIODIDE CATGUT

(Morley's Process)

"A short length of London Hospital Biniodide Catgut was placed in agar-agar thickly sown with aerobic spores and incubated. The inhibiting action of Biniodide in the catgut not only prevented invasion but exerted a local bactericidal action in the infected agar-agar for a distance of from 5 m.m. to 9 m.m. round the ligature."

Members of the profession are invited to visit the department at the London Hospital, Whitechapel, to inspect the process of manufacture throughout.

A Sample and Descriptive Booklet will be sent post free on application to

ALLEN & HANBURYS LTD.
48 Wigmore Street, London, W.1.

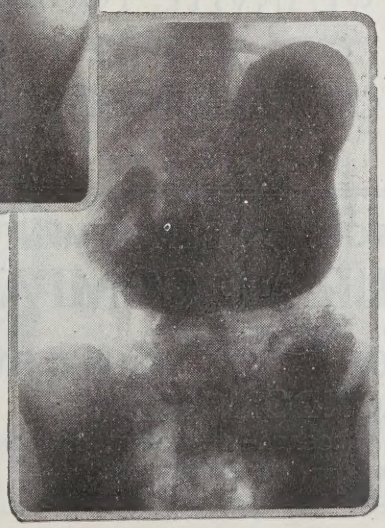
The London Hospital Catgut may be obtained from all the leading Surgical Equipment Houses

"UMBROSE"

(Registered Trade Mark)

(Shadow Meal)

A Specially Prepared Barium Meal for X-Ray Diagnosis



These illustrations are reproductions of the actual work of an eminent London radiologist who employs "Umbrose" Shadow Meal as a matter of routine.

Fully descriptive literature on "Umbrose" will be gladly sent on request.

The high degree of opacity of "Umbrose" ensures perfect shadow definition on the X-Ray plate. Other notable advantages of this meal are its freedom from toxicity, exceptional fineness, palatability, and the fact that it may be simply and quickly prepared in the X-ray room.

"Umbrose" (Shadow Meal) is prepared in three sizes as follows:

No. 1 contains 2 oz. $BaSO_4$
No. 2 „ 4 oz. „
No. 3 „ 6 oz. „

TRADE 'ERNUTIN' MARK

'ERNUTIN' is a chemically standardised preparation presenting the active therapeutic principle of Ergot—Ergotoxine—together with 'Ergamine' and 'Tyramine,' in stable solution and in a state of chemical purity.

This distinguishes 'ERNUTIN' from the many galenical preparations of Ergot which have been found to be seriously deficient in activity. 'ERNUTIN' is of unvarying strength and its use ensures definite physiological response.

For Oral Administration: 'ERNUTIN' (Oral), in bottles of 30 c.c., 4 fl. oz. and 16 fl. oz., at **2/6, 7/6** and **25/-** each respectively. A palatable fluid, which does not produce nausea.

For Hypodermic and Intramuscular Injection: 'HYPOLOID' 'ERNUTIN,' in boxes of six hermetically-sealed containers of 0·6 c.c. (approx. min. 10) of Sterile Solution, at **3/4** per box.

TRADE MARK 'WELLCOME' BRAND

ERGOTOXINE ETHANESULPHONATE

This salt, originated by Burroughs Wellcome & Co., presents Ergotoxine (the specific alkaloid of Ergot of Rye) in the purest state yet attained. It is white, crystalline, stable and more soluble than the phosphate.

ANCIENT ROMAN VOTIVE OFFERINGS, CONSISTING OF MODELS REPRESENTING PARTS OF THE HUMAN BODY.—The custom of making offerings to the gods was inherited by the Romans, who called the objects presented *donaria*. Their motive was chiefly thanksgiving and prayer, but also sometimes propitiation. A very wealthy individual or a state might build a temple or a shrine and dedicate it to the service of the god, but the great majority of people would offer some small representation which served to indicate the subject of the prayer or thanksgiving. Thus there have come to light many figures of armed warriors, farmers milking cows, spoils of war, weapons, tools, sickles, wine-presses, surgical instruments, etc. In addition, great numbers of images of parts of the human body were deposited in the temples of the healing gods, as thank-offerings for deliverance from sickness or in anticipation of cure. The organ or limb affected was represented, either in order to demonstrate the nature of the malady cured, or, when offered in appeal, to ensure that the deity should be left in no doubt as to the particular service sought. Among the most common ex-votos of medical interest were models of eyes, ears, the human trunk, coils of intestines, genitalia, the uterus, ovaries, kidneys, livers and breasts. They were made of terra-cotta, marble or metal, and were generally very poorly constructed from the point of view of anatomy. Some, however, showed considerable skill—a fact which has given rise to the suggestion that these constitute a pioneer attempt at anatomical illustration. Perhaps most frequently the potters who moulded the organs merely made rough copies from glimpses gained of the viscera of sacrificial animals or from examinations in butchers' shops. The intestinal tract here reproduced would seem to indicate a knowledge of human anatomy.

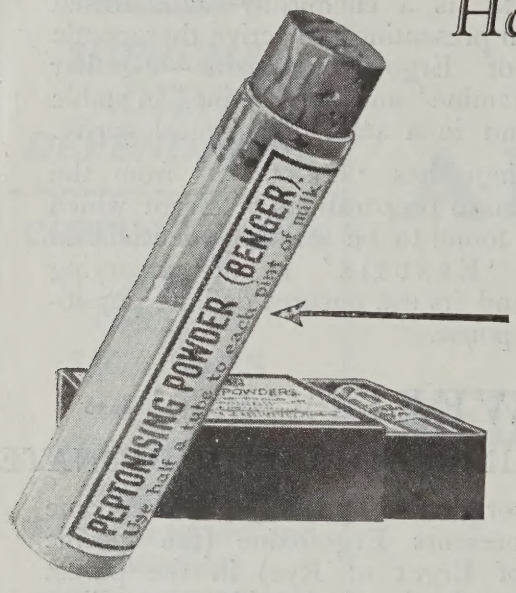
COPYRIGHT

The most efficient Peptonising Powders!



Half a tube of Benger's is enough!

While half a tube of Benger's Peptonising Powders is enough to peptonise a pint of milk, gruel or soup, in most cases in 10 minutes, the extent of the peptonising action can be regulated by either increasing or diminishing the quantity of the powders, and by lengthening or shortening the time during which they are allowed to act on the milk, gruel, etc.

Generally speaking, Benger's Peptonising Powders produce the required result with half the quantity necessary of other preparations, whose initial cost also is higher.

Prices:
No. 1 — Box of 6, 1/-; No. 2 — Box of 12, 1/8

Benger's Liquor Pancreaticus.

An important aid in the preparation of Peptonised Milk, etc.

Benger's Liquor Pancreaticus is an active solution of the digestive principles of the Pancreas; a really efficient agent for the digestion of milk, gruel, and farinaceous or partly farinaceous foods. Benger's Liquor Pancreaticus is odourless and tasteless.

In 4, 8 and 16-oz. bottles.

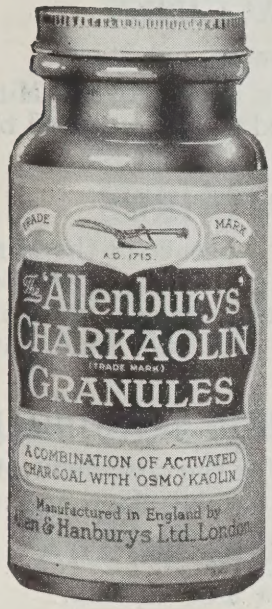
The 'Allenburys'



'CHARKAOLIN' GRANULES

A Combination of Highly Activated Charcoal with 'Osmo' Kaolin

'Charkaolin' is a new and highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of 'Osmo' Kaolin. It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. 'Charkaolin' is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

ALLEN & HANBURYS Ltd., Bethnal Green, E.2

The 'Allenburys' *Sugarless Fruit* PASTILLES

One Flavour only

At the request of several physicians a notable addition has been made to the well-known series of 'Allenburys' Pastilles. This is a pastille with a delightful fruit flavour yet entirely free from sugar. It is specially designed for diabetics and others on a restricted carbohydrate régime and can be eaten freely without harmful effect. The 'Allenburys' Sugarless Pastille maintains the high standard of excellence associated with the 'Allenburys' products and can be recommended to patients with confidence.

In tins containing 4 ozs. and 1 lb.

ORAL SEPSIS.

"EUMENTHOL JUJUBES"

(HUDSON)

Made in Australia.

A Gum pastille containing the active constituents of well-known Antiseptics, Eucalyptus Polybractea (a well-rectified Oil free from aldehydes (especially valeric aldehyde), which make themselves unpleasantly noticeable in crude oils by their tendency to produce coughing), Thymus Vulg., Pinus Sylvestris, Mentha Arv., with Benzo-borate of Sodium, &c., they exhibit the antiseptic properties in a fragrant and efficient form. Non-coagulant antiseptic and prophylactic, reducing sensibility of mucous membrane.

THE LANCET says:—

"In the experiments tried the Jujube proved to be as effective bactericidally as is Creosote."

Mr. W. A. DIXON, F.I.C., F.C.S.,

Public Analyst of Sydney, after making exhaustive tests says:—

"There is no doubt but that 'Eumenthol' Jujubes have a wonderful effect in the destruction of bacteria and preventing their growth. . . . . I have made a comparative test of 'Eumenthol' Jujubes and Creosote, and find that there is little difference in their bactericidal action."

THE PRACTITIONER says:—

"They are recommended for use in cases of oral sepsis, a condition to which much attention has been called in recent years as a source of gastric troubles and general constitutional disturbance, and are also useful in tonsillitis, pharyngitis, &c.

THE AUSTRALASIAN MEDICAL GAZETTE states:—

"Should prove of great service."

IRVING'S

YEAST-VITE TABLETS

The New Yeast Vitamin Treatment.

We hold high medical testimony showing efficacy in cases of **SEPTICÆMIA, PYÆMIA,** skin blemishes and other disorders of the blood.

They act with quick stimulating effect on the pancreas, liver and kidneys.

The antipyretic, anodyne and analgesic action is more pronounced than that of the usual coal tar derivatives, without unfavourable reaction, and have the advantage of rapid assimilation.

Of value as a vitaliser and rejuvenator.

Recommended as a nerve sedative, and of considerable value in moderating menstrual and labour pains.

We supply (without charge) to physicians, hospitals, clinics and nurses sufficient supplies for exhaustive tests.

Intestinal Disinfection

BACILLUS COLI BACILLURIA AND URINARY INFECTIONS

CONDITIONS dependent upon infection of the urinary tract by *B. coli* are by no means uncommon, and present varying degrees of severity, from serious suppurative lesions of the kidney to mild bacilluria of little importance.

The mechanism of infection by *B. coli* in these cases is uncertain, but it may depend upon minute lesions of the mucous membrane of the bowel through which it passes, together with probably an increase in the numbers of a particular and more virulent type (hæmolytic varieties of *B. coli* are common in urinary infections in the male).

If, then, disinfection of the intestinal canal is accomplished, these forms are destroyed, and those already located in the urinary tract may be attacked by a urinary antiseptic. By the combined administration of Kerol, urotropin (hexamine) and acid sodium phosphate, the treatment of urinary infections by *B. coli* is placed on a rational basis, and many cases are cured by this line of treatment when they fail to yield to urotropin alone.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK STREET, LONDON, W.1

Telephone: LANGHAM 1166.

***WHY FAIL** at the **F.R.C.S.** England (Primary or Final)?*

Enrol now for the Oral and Postal Revision Classes and make sure of success.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Exams. on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S. England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise and up to date, and the test questions are carefully selected from those set at previous Examinations so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time and much unnecessary reading is saved

VALUABLE BOOK

"How to Pass the F.R.C.S." free on application to the Secretary. Also Free Guide to all Medical Exams.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

PRESIDENT: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., C.B.E.
MEDICAL SUPERINTENDENT: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, bio-chemical, bacteriological and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

RECEPTION HOSPITAL

There is a Reception Hospital, in detached grounds with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, &c. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for bio-chemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm, gardens and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts such as carpentry, &c.

For terms and further particulars apply to the Medical Superintendent (TELEPHONE: No. 56 Northampton) who can be seen in London by appointment.

BETHLEM ROYAL HOSPITAL, LAMBETH ROAD, S.E.1

(For the Reception and Treatment of cases of Nervous and Mental Disease). *Telephone: Reliance 2182.*

President: COL. and ALDERMAN SIR CHARLES CHEERS WAKEFIELD, Bart., C.B.E.
Treasurer: SIR LIONEL L. FAUDEL-PHILLIPS, Bart.
Physician Superintendent: J. G. PORTER PHILLIPS, M.D., F.R.C.P. Assisted by Physicians, a Pathologist, and a Staff of Visiting Consultants.

Patients of the **educated classes, in a presumably curable condition,** are eligible for admission. With a view to the early treatment of eligible cases **Voluntary or Uncertified** Patients are admitted. **Patients who can contribute 3 guineas weekly towards the cost of maintenance may be received as vacancies arise.** Treatment is carried out on the most modern principles. In connection with this Hospital there is a Convalescent Home on the Surrey hills at Witley.

For further particulars apply to the Physician Superintendent.

PECKHAM HOUSE, 112, Peckham Road, London, S.E. 15

Telegrams: "Alleviated, London." **Telephone: Rodney 4741 & 4742.**

The above House, which was established in 1826, is an Institution for the care and treatment of persons suffering from mental diseases and nervous disorders. Both certified patients and Voluntary Boarders are received. Separate houses for the treatment of special and suitable cases adjoin the Institution. There is a seaside branch to which holiday parties are sent during the Summer months. Motor and carriage exercise is provided as required. Patients can avail themselves of a course of physical drill. Tennis courts, Entertainments, dances, and indoor amusements held throughout the year.

Illustrated prospectus and further particulars can be obtained from the MEDICAL SUPERINTENDENT.

HARROGATE CORPORATION

F. J. C. BROOME,
General Manager of Wells & Baths

THE ROYAL BATHS,
HARROGATE.

JUNE, 1928

Dear Sir,

AN INVITATION TO VISIT HARROGATE.

We are constantly advertising that Harrogate is a BRITISH Spa that offers a "Cure" and a Holiday unsurpassed at any Foreign Resort but unfortunately advertising not being altogether free from exaggeration, our claims may leave you unconvinced.

To prove our point and to gain your goodwill for a BRITISH Spa we ask you to pay Harrogate a visit to satisfy yourself as to what we are doing and how we do it.

Upon receipt of an enquiry, a list of the concessions we ask you to accept during your stay, and Medical and "Lay" Literature, etc. will be sent you by return of post.

I am,
Yours truly,

F. J. C. Broome.

General Manager.

Pullman and Fast Restaurant Car Trains daily, from Kings Cross Station, London.

RESEARCH STUDENTSHIP IN HELMINTHOLOGY.

Applications are invited for a whole-time Research Studentship in the Department of *HELMINTHOLOGY* of the value of £250 per annum, tenable from 1st October, 1928.

The Studentship will be held normally for a period of two years, and is subject to a probationary period of one term of twenty weeks, for which proportionate remuneration at the rate of £250 a year will be paid.

The holder of the Studentship is required to give assistance to the Head of the Department during the actual progress of the course of study in each term, but for a substantial part of each term will be engaged upon research.

Applications should be addressed to the Secretary of the School at 25, Gordon-street, London, W.C.1. (from whom further particulars can be obtained), and should be received not later than 14th July, 1928.

Woolwich Union.

SECOND ASSISTANT MEDICAL OFFICER.

A Second Assistant Medical Officer (Male) is required at the PLUMSTEAD AND DISTRICT HOSPITAL, Plumstead High-street, S.E.18.

Candidates must be single men and be doubly qualified and registered.

The person appointed must have held a position as House Surgeon and House Physician, and have had practical experience in Gynecology and Obstetrics. He will be required to carry out such duties as may be assigned to him by the Medical Superintendent, and should occasion arise, to assist at any of the other establishments under the control of the Guardians.

Salary £350, rising £25 annually to £400, with residence and rations, subject to deductions under the Poor-law Officers' Superannuation Act.

Further particulars of the appointment may be obtained by personal application to the Medical Superintendent between the hours of 10 A.M. and 12 noon, or by letter.

Applications, upon forms to be obtained from my office as under, upon receipt of a stamped, addressed foolscap envelope, or by personal application, must be returned to me not later than the 6th July, 1928.

By order.
ARTHUR HOLDER, Clerk to the Guardians.
Union Offices, Plumstead High-street, S.E.18,
18th June, 1928

Royal Free Hospital, Gray's Inn-road, W.C.1.

Intending candidates should submit applications, stating age and qualifications, to the undersigned on or before 7th July 1928. Preference will be given to former students of the Hospital.

REGINALD R. GARRATT, Secretary.

London Jewish Hospital, Stepney Green, E.1.

The Council of Management invite applications for the post of HONORARY RADIOLOGIST, who will be required to attend the Hospital on three half-days each week.

Candidates desiring to make application must send twenty copies of their application, with copies of three recent testimonials, to the Secretary at the Hospital on or before Friday, the 20th July, 1928.

Saint Mark's Hospital for Cancer, FISTULA & OTHER DISEASES OF THE RECTUM, City road, London, E.C.1.

RESIDENT SURGICAL OFFICER (Male) required. Must be fully qualified. Salary £150 per annum and certain emoluments, with board, residence, and laundry.

The appointment is for a minimum of six months from 1st September next.

Applications, with copies of testimonials, must reach the Secretary (from whom further particulars may be obtained) not later than 9th July, 1928.

St. Mary's Hospital, W. 2.

DENTAL SURGEON.

Applications are invited for the vacancy which has occurred in the office of Dental Surgeon.

Candidates are requested to forward their applications, with copies of testimonials not exceeding six in number, addressed to the Secretary at the Hospital on or before Saturday, 14th July, 1928.

The Dental Surgeon must hold registered qualifications in Medicine and Surgery.

The appointment will be for five years, at the expiration of which term the holder will be eligible for re-election.

By order.

W. PARKES, Secretary.

Commissions in the Royal Army MEDICAL CORPS.

A limited number of Commissions in the Royal Army Medical Corps, not exceeding 25, will be offered in July, 1928.

Applications for consideration should reach the War Office not later than 20th July, 1928.

Candidates must be under twenty-eight years of age on 31st July, 1928, and will be required to present themselves in London for interview and medical examination towards the end of July.

There will be no Entrance Examination.

Full particulars as to conditions of Service and emoluments may be obtained on written or personal application to the Under Secretary of State, War Office, (A.M.D.1.), Whitehall, London, S.W.1.

£350 SURGICAL SCHOLARSHIP.

The Association of Surgeons of Great BRITAIN AND IRELAND invite applications for a Surgical Scholarship of the value of £350 to be held for one year. The object of the Scholarship is to enable the holder to pursue a definite line of research or to study surgery in specified clinics, either at home or abroad.

Candidates in their applications are required to state the line of research or study that they intend to pursue and also to give a résumé of their past careers. No testimonials should be sent but each candidate is required to provide letters of recommendation, to be forwarded under separate cover, from two Sponsors.

The election will be made in November, 1928, and applications must be forwarded to the Secretary of the Association by September 30th, 1928.

E. C. HUGHES, Hon. Secretary.
The Association of Surgeons,
17, Wimpole-street, London, W.1.

West London Hospital, Hammersmith-road, W.6. (226 Beds).

Applications are invited for the post of RESIDENT ASSISTANT SURGEON from 1st August. Salary at the rate of £200 per annum with board, lodgings, and washing allowance. The appointment will be for one year terminable by one month's notice on either side, and subject to annual re-election, may be extended to not more than three years. Candidates must be duly qualified Medical Practitioners and it is desirable that they should hold the F.R.C.S. (England) Diploma.

Applications, accompanied by copies of testimonials, must reach me not later than 1st post on Thursday, 19th July. Candidates must attend a Special Meeting of the Medical Council on Friday, 20th July, at 4.30 P.M. and prior to that date call upon and send copies of application and testimonials to each member thereof. They must not canvass Members of the Board, but, if notified, must attend a Meeting of the Board at 5 P.M. on Tuesday, 24th July, when the election will be made.

H. A. MADGE, Secretary.

Central London Ophthalmic Hospital, Judd-street, W.C.1.

There is a vacancy for the post of PATHOLOGIST. Candidates, who must be duly registered Medical Practitioners, must be willing to attend the Hospital three days in the week. Honorarium £75 per annum. The appointment will be for one year (subject to re-election). Applications, with testimonials, must be sent to the undersigned not later than July 14th.

H. R. S. DRUCE, Secretary.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.1.

JUNIOR HOUSE SURGEON required to commence duty on August 1st. Salary at the rate of £50 per annum, with board and residence in the Hospital. Applications, with testimonials, from duly qualified candidates, must be sent to the undersigned not later than July 14th.

H. R. S. DRUCE, Secretary.

Appointment of Clinical Tuberculosis. OFFICER.

Applications are invited for the above appointment in connection with the HACKNEY AND STOKE NEWINGTON TUBERCULOSIS DISPENSARY, at the METROPOLITAN HOSPITAL, Kingsland-road, E.8.

Candidates must—

(*a*) Be registered Medical Practitioners, and not over forty-five years of age.
(*b*) Have held a House or other appointment in a General Hospital for not less than six months.
(*c*) Have had practical experience in the diagnosis and treatment of Tuberculosis in Sanatoria or elsewhere.

The possession of a Diploma in Public Health and practical experience in bacteriological work will be deemed additional qualifications for the post.

The successful candidate will be required to devote the whole of his time to the duties of the post.

Salary will be at the rate of £750 per annum, rising to £850 per annum by two annual increments of £50.

The appointment will be determined by three months' notice on either side.

Applications, stating age, qualifications, and previous experience, accompanied by copies of not more than three recent testimonials, to be forwarded to the undersigned at the Metropolitan Hospital, E.8., not later than first post on Monday the 9th July, 1928, endorsed "Appointment of Tuberculosis Officer."

Canvassing is strictly prohibited, and will be deemed a disqualification. (Signed) HERBERT F. RUTHERFORD.
Secretary to the Joint Dispensary Committee.

Hackney Hospital.

INCREASE OF MEDICAL STAFF.

The Board of Guardians invite applications from duly qualified gentlemen for the positions of JUNIOR ASSISTANT MEDICAL OFFICERS (two).

Candidates must be single. For one position the candidate must have held a Resident Medical appointment in a Hospital, and for the other position the candidate must have held a Resident Surgical appointment in a Hospital.

The Hospital, which is situated at High-street, Homerton, E, contains 800 beds, and is equipped with modern requirements.

The Staff consists of a Medical Superintendent, a Deputy Resident Medical Superintendent, two Senior Resident Medical Officers, three Junior Resident Medical Officers, a Clinical Pathologist, and a consulting Radiologist.

The remuneration is at the rate of £350 per annum, rising at the end of one year to £375 per annum, together with rations, washing, furnished apartments, and attendance.

The officers appointed will be required to render assistance at the other establishments and departments of the Union, to assist in the training and instruction of Nurses and to devote their whole time to the service of the Guardians.

The appointment will be subject to the provisions of the Poor Law Officers' Superannuation Act, 1896.

Further particulars as to the duties may be obtained from the Medical Superintendent.

Canvassing the Guardians, directly or indirectly, will disqualify candidates.

Applications must be made on forms which are obtainable from the undersigned. The forms must be completed and returned, with copies of not more than three recent testimonials, by Friday, the 6th July, 1928.

By order.
E. W. HARBOUR, Clerk to the Guardians.

Clerk's Offices, Hackney Union,
2, Sidney-road, Homerton, E.9.

County Borough of Blackburn.

ASSISTANT DENTIST.

Applications are invited from Dental Practitioners holding a registered Diploma or Degree in Dental Surgery who are willing to undertake the Dental Treatment of School Children, Expectant and Nursing Mothers, and of Tuberculous Patients. Salary will be at the rate of £475 per annum, rising at the end of twelve months' satisfactory service to a maximum of £500 per annum. Forms of application, which must be returned by the 12th July, 1928, may be obtained from the Medical Officer of Health, Health Offices, Victoria-street, Blackburn.

J. F. CARR, Director of Education.

The University of Manchester.

Applications are invited for the post of READER in Materia Medica and Therapeutics. Stipend £800 per annum. Duties to commence September 29th, 1928. Last date for applications, July 7th. Further particulars may be obtained from the Registrar.

City and County of Kingston-upon-HULL and HULL AND GOOLE PORT SANITARY AUTHORITY.

Applications are invited from Medical Men, under forty years of age, for an appointment as ASSISTANT MEDICAL OFFICER OF HEALTH.

Salary £600 per annum, increasing by annual increments of £25 to a maximum of £700 per annum.

Applicants must be duly registered Medical Practitioners of at least three years' standing and holding a Diploma in Public Health.

The successful candidate will be required to devote the whole of his time to the duties of his office; he will be engaged mainly in School Medical Work, but he will also be required to undertake duty in any section of the Health Services of the City or Port. Candidates must have had special experience in Pædiatrics and be able to undertake Refraction work. Preference will be given to candidates who have a certificate for the treatment of Venereal Diseases and who have had experience in Tuberculosis work.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Further particulars of the duties and conditions of service and orms of application can be obtained on application to the undersigned.

Completed applications, together with copies of three recent testimonials, must reach me not later than the first post on Thursday, 5th July, 1928.

W. ALLEN DALEY, Medical Officer of Health.

Guildhall, Hull.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of a Male Assistant Medical Officer. Candidates must possess a qualification in Public Health, and have had experience in the medical inspection of school children, maternity and child welfare, and the treatment of tuberculosis and venereal diseases. The officer appointed will be required to undertake such other public health duties as may be allocated to him. He will be on the staff of the County Medical Officer of Health, must reside in the County, and devote his whole time to the work. Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the Standing Orders of the Council, which provide, inter alia, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, 5, Grove-crescent, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day for receipt of applications, Friday, 6th July, 1928. Canvassing, directly or indirectly, will disqualify.

DUDLEY AUKLAND, Clerk of the County Council.

County Hall, Kingston-upon-Thames, 13th June, 1928.

Surrey County Council.

DEPUTY COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited for the appointment of Deputy County Medical Officer of Health at a salary of £1000 per annum, together with subsistence and travelling expenses in accordance with the Council's scale.

Candidates must be registered Medical Practitioners with a public health qualification, and preferably be about thirty-five years of age.

Practical experience in the work of a public health department is essential. The successful candidate will be required to assist in the duties pertaining to the office of County Medical Officer, under whose control he will act, and to devote the whole of his time to the work.

The appointment will be subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the Standing Orders of the Council, which provide, inter alia, that appointments may be determined at any time by three months' written notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, 5, Grove-crescent, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day for receipt of applications, Friday, 6th July, 1928. Canvassing, directly or indirectly, will disqualify.

DUDLEY AUKLAND, Clerk of the County Council.

County Hall, Kingston-upon Thames, 13th June, 1928.

Burton-on-Trent General Infirmary.

HOUSE SURGEON.

Private Practice is allowed so long as it does not interfere with hospital duties. The selected candidate will be subject to leave rules under Fundamental Rules. Applicants should possess one of the higher British qualifications and must be competent Surgeons. Only those who possess these qualifications need apply to the undersigned before 31st July, 1928, furnishing the following particulars:—

(*a*) Full name.
(*b*) Date of birth.
(*c*) Nationality and whether of Asiatic or non-Asiatic Domicile.
(*d*) Professional qualifications with dates of obtaining the same.
(*e*) Posts held after qualification and previous experience, with testimonials, if any.

The selected candidate will be appointed on probation for two years, and will be confirmed if found satisfactory.

Signed, JELAL M. SHAH, Major, I.M.S.,
Personal Assistant to the Surgeon-General with the Government of Bombay, Poona (India).

INDIAN MEDICAL SERVICE

RECRUITMENT OF EUROPEAN OFFICERS

Applications are invited from Medical Men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service or £2,500 after 12 years' service, together with free return passages for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian Service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of Civil Officials and for general medical administrative purposes; to specialist (e.g., Public Health and Bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:—

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut...	—	500	150	1st
			150	2nd
			150	3rd
Capt...	(i) During first 3 years' service as Captain ..	650	150	4th
			150	5th
			150	6th
	(ii) With more than 3 and less than 6 years' service as Captain	750	250	7th
			250	8th
			250	9th
	(iii) With more than 6 years' service as Captain	850	250	10th
			250	11th
			300	12th
Major..	(i) During first 3 years' service as Major ..	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major..	1250	300	13th and over.
Lt.-Col.	(i) Until completion of 23 years' total service ..	1500		
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service ..	1700		
	(iv) When selected for increased pay	1850		

Extras.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the War as a medical or combatant officer or in a position usually filled by an officer may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the War may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:—

	Per annum.
After 17 years' service for pension	£400
„ 18 „ „	430
„ 19 „ „	460
„ 20 „ „	500
„ 21 „ „	540
„ 22 „ „	580
„ 23 „ „	620
„ 24 „ „	660
„ 25 „ „	700
„ 26 „ „	750
„ 27 „ „	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919, to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially with effect from July 1st, 1927. A reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the UNDER-SECRETARY OF STATE FOR INDIA, MILITARY DEPARTMENT, INDIA OFFICE, LONDON, S.W.1. Applications should be submitted by the 14th July.

About 15 cases p.a. Pretty residence with ample surgery accommodation (separate entrance), 3 reception, 7 bedrooms, bathrooms, &c. Good garden with tennis court. Garage. Vendor's freehold price £3000. Premium £1800. Social and excellent educational facilities. Cottage Hospital. Satisfactory reasons for selling.
12. NOTTS.—COUNTRY TOWN.—Old-estab. mixed general PRACTICE in hunting country. Average income about £1200 and increasing, including appointments of £200 and panel of 850. Advice and medicine 2s. 6d., visits 5s. to 10s. Good house with garden and tennis lawn. Price for freehold £2200: or a similar house could be obtained on lease at a rental of about £50 p.a. Prem. 1½ years' purchase.
13. WILTS.—Unopposed Country PRACTICE. Old-estab., and averaging for the last year over £600, including panel of 500. Fees 2s. 6d. to 12s. 6d. Midwifery 3 to 5 gns; about 12 cases yearly. Very suitable house with 2 reception, 6 bedrooms, &c., and professional rooms. 1 acre of garden and paddock. Garage. Price £1200. Premium £900.
14. SOUTH WALES. PLEASANT COUNTRY TOWN.—Old-estab. middle-class PRACTICE. Income £1000 p.a. Panel of 500. Surgery fees from 2s. 6d., visits from 5s., medicine extra. Good house, excellently situated, electric light, large garden. Vendor's freehold. Good sport. Good schools. Premium for practice and house £2000.
15. NORTH CORNWALL.—PARTNERSHIP, with succession in one or two years. Well-estab. Practice, in popular seaside resort. Receipts for immediate past year £4400, and steadily increasing. Panel of 500. Fees from 5s. to 2 gns. Scope for major surgery, eye, X-ray and electrical work. Premium 2 years' purchase.
16. NORTH-WEST OF ENGLAND.—Large town, near Coast. Very old-estab. mixed general PRACTICE, held by the Vendor for nine years. Income for last year over £2700, and increasing. Panel of about 840. No appointments. Fees 3s. 6d. to 10s. 6d. Very little midwifery from 3 gns. Exceptionally good well-situated house; will be let on lease. Considerable scope for electro-therapeutic and ear, nose, and throat work, and some surgery. Premium 1½ years' purchase, part by arrangement.
17. CENTRAL WALES.—Good Hospital Town.—Old-estab. non-dispensing PRACTICE. Income over £1400, including £130 from appts. and panel of 500. Fees 5s. to 42s. Little Midwifery. Good house in centre of town, with pleasant garden. Price for freehold £1500. Premium £2100. Exceptional scope for surgery.
18. DEVONSHIRE.—Very old-estab. unopposed Country PRACTICE in up-to-date village offering exceptional facilities and amenities, in pretty district within few miles of large town. Receipts for past 3 years average about £1450 p.a., including union and vaccination £66 and panel of 530. Visits 3s. 6d. to 21s. Midwifery discouraged. Charming residence in own grounds of about 2 acres with ample accommodation. Electric light. Rent £50. Premium 1½ years' purchase. Good society and sport.
19. ESSEX COAST.—Favourite Resort.—PARTNERSHIP.—A one-third share, to commence with, in an old-estab. Middle-class Practice. Average income of about £2800. Panel of 600. Visits 4s. 6d. to 21s. Little Midwifery. Suitable accommodation can be obtained. Premium 2 years' purchase.
20. CORNWALL.—Hospital Town, near Sea.—A five-thirty-seconds SHARE, to commence with, is for disposal in a sound mixed better- and middle-class Practice. Average income for the last 2 years about £5100, including panel of 3700. Surgery fees 2s. 6d. to 10s. 6d., visits 3s. 6d. to 15s. with medicine extra. Small convenient house with garden and garage. Can be rented on lease at £85 p.a., or would be sold for £1500. Premium 2 years' purchase.

Full Schedule of Terms and Conditions will be forwarded on application.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(Founded 1880)

Tele Address: Triform, Wesdo—London. **12, Stratford Place, Oxford Street, W.1.** Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the British Medical Association has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

MEMBERS OF THE BRITISH MEDICAL ASSOCIATION MAY TAKE ADVANTAGE OF A REDUCED SCALE OF CHARGES APPLICABLE TO THEM.

For the sake of reference the business undertaken by the BRITISH MEDICAL BUREAU is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the BRITISH MEDICAL BUREAU. Vendors may depend upon receiving introductions only to eligible and bona fide purchasers. All information is treated in strictest confidence.

Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the BRITISH MEDICAL BUREAU to ensure that only the most TRUSTWORTHY AND RELIABLE Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the BRITISH MEDICAL BUREAU. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The BRITISH MEDICAL BUREAU has its own staff of fully qualified Accountants wholly engaged on Medical work, i.e., Investigation of Practices for purchasers, Income Tax, Auditing books and accounts, etc.

SCHOLASTIC DEPARTMENT.

Medical Men will find this Department of the BRITISH MEDICAL BUREAU of great assistance in the selection of Educational Establishments, Private Tutors, Governesses, etc. Prospectuses and advice gratis.

All correspondence and applications should be addressed to **A. V. STOREY, General Manager.**

BANK LOANS FOR PURCHASE OF PRACTICES OR SHARES

We assist Doctors to purchase General Practices or Partnership Shares.

LOANS can be secured from A LEADING BANK at 5½% per ann. up to *two-thirds* of the purchase price on the guarantee of a FIRST-CLASS INSURANCE COMPANY, for whom we act as SOLE AGENTS for these special guarantees.

REPAYMENTS can be made over 5, 6, or 7 years.

A Doctor desirous of INCREASING his SHARE, or wishing to BUY OUT a PARTNER will find our BANK LOAN arrangement excellent.

NO PERSONAL SURETIES OR GUARANTORS ARE REQUIRED.
